I think I would begin by placing the radials on (or in) the ground where they'll do some good for you--rather than resonating them so they can add excessive ground loss to your system. Get a cheap Black&Decker electric lawn edger and cut neat little slits for them.

David:
Check with your local electrical supply company or hardware store.
What I think you are after is what is called a "Direct burial ground rod clamp."

They are made of bronze and will have no adverse reaction to copper wire or ground rods. That is what I use and have seen no problems.

To avoid electrolysis corrosion use materials which are near each other on the galvanic chart. Copper and aluminum are far apart (aluminum being the highest) and will have an adverse reaction with the aluminum being the sacrificial element.

Hello volunteer,

I already have selected my charity where I prefer to expend my voluntary effort. Perhaps someone else here?

Maybe I went to a group that was even less funded, but they got my money, too, through positive relations.

Who but a volunteer would venture into fractal design with such hostility surrounding the topic? :->

OK, so I'm a fool - who still feels volunteerism is important.

Hello All!

This is not an antenna question, as much as it is a reception question. My wife and I have just moved into our first home; the only place in the garage where I could put my R-71A receiver is on the other side of the living room wall. Right! Just behind the rear of the t.v!

Each time she turns the t.v. on, it wipes out my reception!

What can I do to mitigate the "buzz" that's generated from the boob tube, short of lining the wall with a lead shield or DX-ing after 10 P.M.?

Many Thanks and 73's

With video, standing waves can cause problems....depending on how long the area is where the reflected waves "stand" and how fast the phase sensitive information changes.

Using Steve's method to look at the line should result in exactly the same results as using your's Cecil, when discussing systems like we normally use at HF. If it doesn't, than something is wrong with someone's method. I know your method works in what I commonly do Cecil.

>Thanks.

You will likely find that the longer lengths don't bother you much.

However in the interest of pristine perfection .. ;)

Instead of cutting them, use an egg insulator at the far end and simply
fold them back on themselves temporarily. Use a rope on the other end
of the egg insulator to play the egg back as you shorten it.

At that point, you can test to your heart's content and not cut any
wire. Lengthen it and shorten it at your whim to fool all you want.

Re tuning this these wires... Since the thing is all interactive due to
coupling and whatever is around the thing .. think about this way...

Another way to do this is to connect a small few turn loop between the
two quarter wave wires connecting them together in the middle. Poke the
snoot of a grid dip oscillator coil into this loop. You can then dip
the frequency of the radial pair with it too!

That's a neat way to tune the loop elements in wire quads too. When I
was playing with them, I used to simply take one corner, side, whatever.
I'd break the loop with a regualr antenna wire steatite insulator.
Between the holes on either end, I'd take #12 or so TWN or whatever.
I'd use a plastic screwdriver handle for a form, winding the large
single strand wire for six or so turns around it. Then I'd form the
ends of the wire through the insulator holes and use Kerney clamps to
attach the free wire ends.

You could poke the grid dipper into this little loop and see a dandy dip at the reasonant freuency of the loop! Pulling the wire shorter on the sides while keeping it long enough, or paying it out would tune the loop.

Another simple trick is to use a short section of ladder line in the middle of this test insulator - going away at right angles to the wire plane. By putting the little coil in series with one leg of the thing, you could adjust the length of the ladder line to raise or lower the frequency of either the loop or the radial pair. For wire beams, this is a neat way to get a three-element array reversed as a fixed array.

You use the ladder line stub to get the longer element lenght needed for the reflector, with the actual wire length the right length for the director. To reverse the throw of a 40 meter or 80 meter quad, simply short across the ladder line at the split off insulator, or open the ladder segement up to make it longer.

Wire quads actually play fairly well close to the ground on 40 and 80 this way, but you have to feed them in vertical polarization mode. They come alive that way! More than three elements fed this way in low band near proximity to the ground is a waste of time. A little modeling with any of the popular programs will show you why in short order!

Cheers ..

Rick .. the elevated four wire deal works beautifully, however I think he will find that the 8 foot height is not helpful. From a *LOT* of use of this array on 40 CW, I can tell from experience that the minimum that he will really see come alive is likely to be 19 feet up or more. That is one reason I ground mounted my 80 meter 4 square, as opposed to elevating it.

From *BITTER* experience, I'll also not the other killer deal here.

As you go up with the elevated radial deal, the lightning strike problem takes on a whole new dimension. That ten feet to the ground at the RF frequence is a whale of a voltage spike at thousands of amperes.

No matter how well you work out a scheme to drain off the hit flow, you wind up with a much tougher job of damping the hit to real ground with the elevated radial game. The only real clean way I ever got away with it was/is to run the shunt feed coax line down to ground, use the appropriate protection there and bury it back to the shack.

I'll, again, state that lets not go into the theory of phased vertical arrays all bonded together with elevated radials here, please. What doe count is that the phasing box, relays, shack entry path for the hits and induction kick stuff, is a lot harder to work with with the elevated radial deal than the other ..

However -- the elvated deal, as long as about an 1/8 wave above ground is used as a mimimum plays *VERY* well on low bands.

My worked total on 40 CW with one is at 314 countries now .. ;)

The 80 game is harder in this Hell they call Sand Soil Texas .. its only about 230 worked on 80 and that one is ground mounted .. ;)

The direction of error makes sense to me. You have a dipole .03 or .04
WL above earth. It will be a lossy system, so the impedance will be
much higher than 50 ohms. Because the system is so close to earth, the
wires will appear electrically much longer than they are physically.

When I install Beverages, I use the same method to determine the
electrical length. I find the Beverage is about 10-15% longer
electrically than it is physically.

How did you "float" the 259 to keep it balanced? Did you let it hang
in the air? Did you use a choke balun of some sort?

The Vf you measured seems pretty slow.

By the way, don't expect high efficiency with your system. You will
have quite a bit of ground loss.

Dick,

I'm already using the bronze ground rod clamps and an anti-corrosive joint compound for the underground wire and rods. All I need is a couple of 3/8" bolts to hold a copper cable clamp to the copper bulkhead (a 20"x4"x1/8" grounding plate with several drilled holes) outside the house where all of the ground rod wires end at a single grounding point. The stainless steel bolts will work for the time being since the clamp and bulkhead are both copper.

> grain of salt. As I recall, his methodology yielded inaccurate data.

Hi, Rick,

That is still under consideration. :-) The inaccuracy, if any, appears to be at the high end of the scale -- ie, a tuner that was listed as having 3 dB loss could be somewhere between 2 and 4 dB, for example. Of course, at 3 dB loss, the tuner would probably be in the unuseable range for most power levels. I believe that the accuracy was acceptable for the lower losses -- the range over which one is going to be able to use the tuner. But, as you may have seen in my other post, I did recommend the article and, in fairness, I didn't want to do so without also mentioning the questions that have been raised. I figure if I am taking the question seriously enough to be looking at alternative methods, that I should at least raise the issue when I recommend the article. (Good science, I guess. :-)).

For the next review, I intend to use other methods to measure the tuner's loss and compare them to the values obtained using the "Witt" method. If there are significant differences, I will either do a sidebar or post some info on the ARRL web about tuner testing or write a QEX article or something. I can't speak for the editor, but I do intend to make the results available publically somehow.

I think the easiest way to measure the insertion loss of the tuner would be to do it at low power, using our signal generator and microwattmeter. If I operate the tuner into an attenuator designed to match N ohms to 50 ohms, I could input say +20 dBm and measure the output accurately, after adding back the loss of the attenuator matching device. Dean Straw suggests doing it with high power, using an RF ammeter to measure the current delivered to specific loads. I will try both, then ask Mr Witt to characterize the tuners for us. Should be an interesting excercise; your input, here, or off-line, is most welcome.

I don't think it's a case of not wanting to hear about fractal antennas, but lots of people are tired of hearing lots & lots of nothing. The main proponent for fractals on this NG won't divulge any info on this NG about his fractal antenna. You have to go join his NG. I know I am always willing to listen & learn but Fractenna won't give anything up here, he just keeps saying stuff like "I'm the greatest & my antenna is the greatest." But no data is shown to back it up. I honestly think that Fractenna might just know a thing or two worth passing on to people like me but if asked, he tends to get rude & tells people to "go look it up" like doesn't want anyone wasting his time. Maybe the NG should split, but not many people are gonna leave this NG & go to another one. In fact, I doubt Fractenna would leave this one. I think he actually enjoys stirring things & pissing people off.
But to summarize, I don't think there's anyone here that wouldn't want a rational, logical discussion about fractal antennas. Too bad it ain't gonna happen.

I am looking for help in finding an indoor antenna for FM reception on my audio receiver. I visited the local Radio Shack today and saw some indoor antennas, but mostly for TV reception.

I tried to connect my Cable TV coax cable to the receiver, but the signals shot-out (no reception at all) . I'm doing something wrong ?

Please help.

Thanks

20. Help with FM Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-01 00:00:00 UTC
From: Emmanuel Sopeju <esopeju@istar.ca>
Message-ID: <vcpfts0mvidbl55vklgtcjkmke47ht00ne@4ax.com>
Source record: 178738

I am looking for help in finding an indoor antenna for FM reception on my audio receiver. I visited the local Radio Shack today and saw some indoor antennas, but mostly for TV reception.

I tried to connect my Cable TV coax cable to the receiver, but the signals shot-out (no reception at all) . I'm I doing something wrong ?

Please help.

Thanks

21. Re: Tower grounding

Another question on this subject- I have read on one of the antenna or Tower reflectors, or on this NG, that stainless foil ("shim-stock") used as an intermediary material , would protect such joints from corrosion. In my case, I have heavily galvanized rods, and heavy copper wire or strap. Is a connection using stainless clamps with stainless foil between the galvanized rod and the copper conductor appropriate? A similar connection will exist where the conductor is connected to the tower leg. I also have available (for the rods) the Bronze clamps normally used.

Message-ID: <39D7EE0F.CE7224DD@eznec.com>
Source record: 178741

I want to thank you for running the numbers. It spurred me to get some more quantitative values myself, and I found I was mistaken in the way the IC730 ALC works.

I have a fairly low 80 meter dipole which is resonant on the lower part of the band. So beginning at resonance, I moved up the band and checked forward and reverse power at several frequencies. Of course, I don't know the impedances being presented to the rig, but they do represent pretty typical conditions under which SWRs higher than 1:1 are encountered.

In the following table, Pf is forward power and Pr reverse power to the antenna at each frequency. Dummy Pf is the forward power to a dummy load at the same frequency, to make sure that the output is reasonably flat with frequency. Dummy load reverse power was zero at all frequencies. The SWR column is the SWR computed from the antenna forward and reverse readings. The frequency range is about 3.69 to 3.99 MHz. My ability to read the meter is within a watt or two at the forward power level, and within a watt at the reverse power level.

Pf Pr Dummy Pf SWR
98 0 99 1
98 5 98 1.58
99 10 97 1.93
100 15 96 2.26
100 20 96 2.62
100 25 95 3.00
100 30 95 3.42

So my rig is behaving like Reg's, and like my homebrew rig -- it's keeping the forward power constant. My earlier statement that it keeps the net power (forward minus reverse) constant was incorrect. The net power does decrease as the SWR increases, although the decrease isn't much, amounting to a little over 1 dB at 3:1.

To answer your question about the Bird wattmeter -- routine calibration or setting isn't required. The meter shows absolute power on a somewhat nonlinear scale, with the scale factor depending on which "slug" is inserted in the meter. (There are slugs for a wide selection of power levels and frequency ranges.) The forward power is read from the meter with the slug in one position, then the slug is rotated 180 degrees to read the reverse power on the same scale. The net power has to be manually computed by subtracting the readings. The specified accuracy of 5% of full scale is too poor for really precise measurement, but resolution is fair, and most meters appear to be much more accurate than the specification indicates. Some of the slop in the spec is undoubtedly

due to the fact that sensitivity varies somewhat over a slug's specified frequency range, and to accommodate all combinations of slugs and meters. All the above applies to the model 43, by far the most common model, and one which has been a standard for decades.

Your measurement method is subject to error from any stray reactance as well as meter inaccuracy, so is probably no better than the Bird. But I think both our sets of measurements show that the rigs are doing a reasonably good job of adjusting their output levels to maintain a constant forward (not to be confused with net) power in the face of varying load impedances.

Good info, Gary--

A few comments--

"Gary Coffman" <ke4zv@bellsouth.net> wrote in message >
> That's about right for a nuclear plant, because primary loop temperature
is
> kept relatively low.

Yes. A nuke operates about about 600 degrees and 1000 psia steam pressure to the turbine. Fossil plants run at about twice that pressure. But I think there's a theoretical limit on the efficiency of a condensing steam turbine anyhow--and there may be more to it than just the energy you have to give up in condensing steam back to water.

>
> (Thermal efficiency is relatively unimportant for a nuclear plant, of
course,
> because fuel costs are a negligible part of their bussbar power cost.

Nuclear fuel costs are far from neglibigle, but they're much less a portion of total production cost in a nuke than in a fossil plant. Thermal efficiency is very important in a nuclear plant though, although it is limited by primary system (reactor) constraints as you said. The NRC licenses a plant at a certain thermal power level in the reactor. How much of that primary power is converted into electrical power is up to the plant owner, and more electrical power is obviously more profit. So plant operators are constantly trying to maintain and improve secondary side efficiency. I'm sure the same is true in fossil plants.

Most of
> the cost is debt service on the horrific capital costs incurred building
them
> in the US. Most of that is due to the average 12 years it takes to get a
plant
> licensed and producing power in the US.

I'm sure there's a lot of deviation from the mean in that 12 year average. You have to decide at what point you throw out the numbers on the plants that *never* come on line. The three I had experience with came on line in about 6 or 7 years.

>Racking up interest for that long before
> generating the first billable kilowatt-hour makes the debt load huge.

That's absolutely true. The anti-nuclear forces back in the seventies didn't have too much luck getting the technology outlawed absolutely, so

their strategy evolved into making it too expensive for any utility to afford. They were pretty successful at that. A good ploy was to get laws enacted that said utilities could not pay anything on a plant until it went on line. The pitch was, "Utilities want YOU to pay for plants that aren't even making power yet! YOU can vote to forbid that." So utilities had to borrow hundreds of millions in the high inflation 70's at 15 to 20% interest for 5 to 10 years." Plants that had cost 400 to 500 million in the early 70s escalated to 3 to 4 billion in the late 70s and 80s. The anti-nuclear forces were successful and as usual, the ratepayers got stuck with the bill. (And with all the extra pollution from the fossil plants that had to be built to compensate.)

By contrast,
> it takes less than 12 months in France, and less than 2 years in Japan to get
> a plant licensed. That makes nuclear power much more economical in those
> countries, France is now 86% nuclear and Japan is over 50% nuclear while
> the US remains less than 6% nuclear.)

Yeah, you hear a lot of good things about programs over there. But in France and Germany they are constantly on the brink of electing regimes that wants to close down their entire nuclear industries. I think the Germans might be there now. And I got to visit some Japanese nuclear plants a few years ago. I was very surprised to learn that their version of the NRC was perhaps more restrictive than ours, and public opinion just as negative. They had no nuclear plants under construction and none on order.

>

> generation, as well as making us more dependent on imported fossil fuels to fire the
> generators. (Clinton/Gore have pronounced domestic coal "too dirty", and are pushing
> for new power plants to be either natural gas or oil fired.)

Yes, its ironic and ridiculous to fret about greenhouse gasses and other fossil fuel related pollution while ignoring a solution that's right under your nose. I've learned that the best the nuclear industry can expect from Washington is benign neglect. That's pretty much what we've gotten from the present admistration and what we got from Reagan-Bush in the 12 years previous. (A lot of my associates cheered in 1980 saying, "Now we've got a pro-nuclear administration. We can expect things to pick up." But

cancellations continued, no new plants were ordered, and there were no new initiatives out of Washington to remove unreasonable restrictions on nuclear power.) There's no political capital to be had in taking a rational stance on nuclear energy, given negative programming of the the average voter's mind back when the anti-nuclear power thing was the "cause of the week."

Murray- for once, dammit, I need to ask that someone re-read a post of
Chips- He DID say he used an attenuator, so 1/2 Watt out is possible.
By strict English usage, of couse, his statement is ambiguous, because
the reference to where "out" is, is open to interpretation (HI).

I think he said he had an attenuator in-line, so the JRC could have
been putting out 5 watts and he stepped it down.

Lam Research at one time used variometers in the matching networks of their 13.56 MHz plasma etch machines. They consisted of nested spherical inductors made of copper tubing. The reason why they did this was to increase the tuning speed compared to a series LC having a vacuum varible for the C. It worked quite well.

They had to have the variometers custom made since you can't buy variometers off the shelf.

One thing you can do is try another AC outlet -- you could be sharing a common
line.
You might also try putting a snap-on choke on the AC line -- maybe even both.
Also, disconnect your antenna and see if the noise is still there. That might
give clues
to the source of the noise, or put a dummy load on the antenna which would be an
even
better test. Even moving the sets a few inches further apart might help if the
receiver is
getting direct radiation from the TV's oscillator. I'm sure there are more
things you can
try -- perhaps others can throw in their ideas. This was just off the top of my
head (where very little is left anyways!). Good Luck!

"Yep" and "yup" are well understood in Old England but are used less frequently than "yes". Their USA slang origin is recognised.

The words are not quite so affirmative as "yes" and have a slightly dismissive flavour. So the vow "Yup I will" from the bridegroom would not be accepted by the bride's father with a loaded shotgun.

But fine between friends.

You pay $34 a year. You get 12 printed, hi-gloss magazines a year in
your mailbox. That's not an unreasonable subscription rate for a
limited-interest specialty magazine. In addition, you get access to
various parts of the arrl.org site, open only to subscribers.

Does qsl.net publish a monthly magazine?

I didn't know QTH.net has a "magazine".

Is it like Antennex, or do they have technical editing of some sort
the keep the bolognia out? Antennex had all that CFA crap going on
for a year, and was selling plans to build the CFA.

Talk about making money without providing anything.

Helical loading is one of the more electrically inefficient was to
load an antenna. It has mechanical advantages, but no electrical
advantage.

It works ok if the antenna is large compared to the wavelength or you
want a skinny structure without a heavy lumped inductor or top hat.

Some people claim it works better because the current distribution is
more like a full size antenna, but that isn't actually true.

VE9SRB wrote:
> In the case of the re-reflected voltage at the match point, it adds to the
> driving voltage and the above formula is correct.

Your formula is irrelevant to the present discussion because the two
voltages associated with the two powers are not driving the same impedance.

It is true (in the example) that the reflected voltage adds to the driving
voltage to get the forward voltage because the forward voltage is known to
be larger than either of the other two voltages. But you cannot extend the
voltage values to the power values unless you take the two different Z0s
into account. Otherwise, you are assuming the proof of an invalid argument.
When you take the two different Z0s into account, you will find:

Pg = Vg^2/50 = Ig^2*(50) = 100w in the example
P+ = V+^2/300 = I+^2*(300) = 200w in the example
P- = V-^2/300 = I-^2*(300) = 100w in the example

Because the reflected voltage and reflected current are 180 degrees out of
phase, if the reflected voltage adds to the driving voltage to get the forward
voltage, then the reflected current must *subtract* from the driving current
to get the forward current. This is consistent because we know that the forward
current is less than the driving current. Thus:

|V+| = |Vg| + |V-| and |I+| = |Ig| - |I-|
Vg*Ig = 100w, V-*I- = 100w, V+*I+ = 200w
Vg/Ig = 50, V-/I- = 300, V+/I+ = 300

This is certainly a less complicated model than an infinite series of
interference patterns and is perfectly consistent with known measurements.

>

'fair use' and 'derivative work'. use of published material is normally legal as long as it is properly attributed (see the "mi2 loop.txt" file in the same directory as the eznec model), and is not a substantial part of the original work. didn't i remember that roy transcribed this from a published article? as such it was surely just a single figure or two in that article and as such would probably be only a small part of the original work. and if the original wires table wasn't published at all as it sounds then there may even be doubt that it could have been copied in the first place. and being 'recognizable' doesn't necessarily prove infringement. the use of the main melody of very recognizable songs is legal for parodies with new lyrics. speaches and recognizable writings are frequently, and legally, modified and published as parodies. copying and quoting technical work of others then improving or adding to it is a standard practice and does not require prior permission unless using a substantial part of the orginal work.

look at this from a more generic point of view with this situation:
1. person-a publishes an article with pictures, graphs, and word descriptions of a design for item-x. they make certain claims that item-x works a particular way. they do not publish their design files or specific parts of them that would let someone else duplicate their work.
2. person-b reads the article and says 'i can do better'. taking the description of item-x and looking at the pictures they reverse engineer item-x and create their own model of how it works in a different (or even the same) modelling program. from that derived model they learn how item-x performs and find that it has some shortcomings and can be done just as well or better a slightly different way.

first, if this were scientific work i would expect person-b to publish their work citing person-a's work and showing how it was wrong or how it could be

improved. this is done all the time in technical journals.

second, if this were a comercial product i would expect person-b to file a patent application with specific improvements on the original design... and if granted and if person-a wanted to use those changes person-a would have to buy them from person-b.

so fire up that patent process roy, you may have something here if fracky is so keen to squash it!

Message-ID: <MPG.1440764e51fe50789896f1@news.gte.net>
Source record: 178826

I just purchased a mini-G5RV antenna (40-10 meters) at the local swap meet. It can fit in my backyard fairly well, BUT....

I may have to have it oriented as a "folded" dipole, because I don't think I can stretch it the full length and keep it hidden within the tree that's camouflaging the back part of our home. If I let it get too far out in the open, I'm liable to have the condo association come down on me. Right now I'm trying to put it up inconspicuously. Looks like it will probably be folded at a 45-degree angle at the feedpoint.

What will "folding" it do in terms of radiating pattern and other operating characteristics?

Thanks in advance for any help you can provide.

You forgot to take the difference in Z0s into account.
One of the 100w values is into a Z0 of 51.5 ohms and the
other is into a Z0 of 300 ohms. Going from a 51.5 ohm environment to a 300 ohm
environment requires a transformation. You are ignoring the transformation
of voltage and current that Mother Nature insists upon when the Z0 changes.

For 100 watts into 51.5 ohms plus 100 watts into 300 ohms to equal 200 watts
into 300 ohms, 71v plus 173v would have to equal 244v and, WONDER OF WONDERS,
it does exactly that. 71^2/50=100 173^2/300=100 244^2/300=200
71+173=244 Funny how that works.

> 2) Transmission line theory demands that the level of power reflection at

> 51.5 ohm line and a 300 ohm line. Transmission line theory tells us that a
> total reflection of power cannot occur at this junction.

Transmission line theory tells us that a reflection will occur at a 51.5/300
ohm junction but there are no reflections on the coax. This says that *total
acceptance* of forward power occurs at a 51.5/300 ohm junction when it is
Z0-matched. If you have total acceptance of forward power on one side of the
Z0-match then you must have total rejection of reflected power on the other
side. This model is consistent, simple, and useful. Why do we need to talk
about an infinite series of interference patterns? What is wrong with assuming
the 1/2WL series section has transformed the impedance to 51.5 ohms thus
making the impedance discontinuity effectively disappear? What mistake have
amateurs been making when they used this concept over the past 70 years.
Would they have radiated any more power if they had adopted your approach?

> So, the correct source
> power delivered into the 300 ohm line is 50 watts not 100 watts.

This is simply not true because we can measure otherwise. We know all the
generated power is delivered to the load in a lossless Z0-matched system.
Source power delivered to the Z0-match is measured at 100w and continues
to be 100w. No amount of words is going to change the meter reading.

We know there are no reflections at the 51.5/300 ohm junction because there
are no reflections on the coax. The generator power has nowhere to go except
into the 300 ohm line. The thing that makes this possible is the impedance
transformation going on in the 300 ohm line. The reflections from the load

arrive at exactly the right phase and magnitude to cancel any reflections that try to happen on the coax. Even your infinite series of interference patterns shows this to be true. THERE IS NO REFLECTED POWER ON THE COAX.

> The source power delivered to the 300 ohm line is 50 watts.

Nope it's not because we can measure otherwise. You cannot source 50 watts and get 100 watts to the load. Are you really pulling our legs with all this perpetual motion stuff?

> Now, the impedance match. How does it occur?

It occurs the same way a stub can be cut to present an impedance other than Z0. The reflected waves transform the 51.5/300 ohm impedance into a 51.5 ohm Z0-match. The forward power from the generator sees a virtual 51.5 ohms at the Z0-match so there are no reflections. Your infinite series of interference patterns shows that the impedance bump at the Z0-match disappears during the transient state and the reflections from the Z0-match become zero. Don't you understand that the phasor addition of two voltages can result in zero voltage and the phasor addition of two currents can result in zero current? There is zero reflected voltage and zero reflected current on the coax after steady-state conditions are reached.

Stubs and series section transformers present virtual impedances to the incident waves. Complete cancellation of reflected power is often the result. Saying the components of the cancelled waves are still there after they have been canceled takes us into the realm of the metaphysical.

>From: Bob Miller bamiller@texas.net

> In addition, you get access to various parts of the arrl.org site, open
> only to subscribers.

Actually, the majority of the ARRL site is open to all comers, not just subscribers. The members-only section includes an online publication, downloads of the past QST Product Reviews and a fully searchable QST/QEX index (with categorization). The majority of the members-only pages are related to the aspect of ARRL that non-members are choosing not to buy -- QST articles. Seems fair to me; if people are not interested in a QST subscription, then it is reasonable to presume that they would not be interested in the articles and indices from same.

>Does qsl.net publish a monthly magazine?

Not to my knowledge; they also do not maintain support for a field organization of volunteers, an educational department that maintains contact and support for school teachers using ham radio in the classroom, a DC office that attends numerous meetings and functions, and prepares comments in defense of amateur spectrum, a technical staff that does the same.

The concept that everything ARRL offers should be free so that some individuals do not have to chip in to help pay for those sorts of things because QSL.NET offers some free things on its web page so it can have enough traffic to charge money for its ads is really mixing apples and oranges, IMHO.

I have to wonder, too, how the QSL.NET pages compare in terms of available articles for download to the 100+ pages and 500+ QST/QEX articles available for download from the ARRL pages at:

http://www.arrl.org/tis

To comment a bit on the previous post:

>>How do they do it? Through subscription and "voluntary"
>>contributions.

Over the years, I have noted that most who say this have not made such voluntary contributions personally. :-)

>>Volunteerism - this seems to be a lost practice for some while an
>>art for others.

In case anyone does not understand, I will add that the ARRL HQ staff is paid; the ARRL Board of Directors -- the ones who set ARRL policy -- are unpaid, and elected by the direct vote of ARRL members.

Hello Cecil--

I sure will, but you're going to need a boiler to power it since my comments were on generators and not on rf amps. My point being that generators are *not* analogous to rf amplifiers in this regard.

BTW--to clarify the truncated quote above, lest anyone think that I stated that the actual source impedance of a generator can be made zero--I didn't. I said that using the "dynamic" method of changing the load and inferring the impedance from the terminal voltage change (which may be as low as zero), could give the false impression that the machine's impedance is zero.

Hi Cecil:

Its been fun.

What you measure and "see" in the transmission line system are the steady state conditions, nothing else. You need to look at the transient response to see what is really happening with wave reflections.

I have no intension of turning this into an argument on points that I know to be so basic to understanding transmission line theory, so I will stop at this message. You have stated your opinion, I mine. We disagree, which is the resolution I expected when we entered into this discussion.

Thanks, Steve

Hi, All Concerned:

Among other things: I notice that Bub, BA, the Boston University Bloviator, By Accolade, aka Sob, the Scourge of Belmont, has been averaging a torrid 1000+ posts a week to wreck.radio.a.a, over the 3 weeks prior to this last, according to Deja stats.

He continues his wreckord pace, according to deja, at 1400 posts this last week. 56 pages of lyrical, deathless prose.

Kewl! That thing can really post! Or, does he have help?

Thought the 'Subject' below was especially appropriate. Bogus???????????

That's true, which is why we don't want any gaps in the path of the lightning discharge. All of the conductors must be securely electrically bonded together.

>Steel is more resistive than copper but lightning is so fleeting that
>the resistive heating in a tower or in the rebars of its base is not
>very impressive.

Yeah, about enough to raise the temperature of a cup of coffee 2 degrees.

>Steel is less resistive than concrete. When lightning strikes the
>concrete will have the larger voltage drop and thus the larger power
>dissipation.

True, which is why we need a lot of contact with a lot of concrete. That spreads the current and prevents any one spot from getting excessively hot. That's what a Ufer is designed to do.

>Concrete is an ongoing chemical reaction between the cement and water in
>the mix which sticks the pieces of aggregate together. At first the
>reaction is rapid. You can feel the heat produced by the reaction in
>fresh concrete. But, as more and more of the constituents gel, fewer
>remain to enter the reaction and the process slows but is NEVER
>completed. Never in a million years, it is believed. So, conductive
>water always remains to provide passage to an electric current.

Concrete never really cures, but after 90 days the amount of free water left in the concrete is very small, a small fraction of one percent of the water used to mix the concrete. The amount of free water continues to decrease, at an exponentially slower rate, for as long as the concrete exists. It will never reach zero, but it will approach zero arbitrarily closely as time goes on.

>Lightning travels between the rebar and the earth through the concrete.
>It finds moisture a better path than other constituents of the concrete.
>Enough resistance is in the water to produce superheated steam as there
>is so much lightning current and such small bubbles of water. Think

>small steam boiler explosions.

The current is carried by the hydrated cement (that's a chemically bonded solid, not a liquid solution). The residual free water in the micropores, each about 20 microns diameter, and isolated from other micropores, is surprisingly pure and doesn't carry much current at all. The presence of the micropores actually serves to reduce the conductivity of the concrete because they can be considered to be tiny insulating spheres embedded in a conductive matrix of cement. To raise the temperature of the water in the micropores, the surrounding cement has to get hot and conduct the heat to the water. Concrete is a relatively poor conductor of heat.

>Concrete is hard to crush, but easily snapped like a Hershey bar if
>subjected to tensile forces. The exploding water bubbles break away the
>seams between vapor cells and crack the concrete.

This doesn't happen, if you spread the currents properly. That's what the bonded rebar cage and the concrete jacket do. By spreading the current through a large volume, current density at any particular spot is kept low. We're effectively dealing with many many resistive paths in parallel. The current divides among these many paths, and the total resistance is small. (Picture millions of 5k ohm resistors in parallel. Total resistance is tiny, and current through any one resistor is also tiny, which gives a tiny I^2 * R heating at any particular spot.)

Lets do some numbers. A properly constructed Ufer should have less than 5 ohms resistance to Earth. Now an average lightning bolt has a current of 18 kA, and a duration of 12 uS. The number of joules dumped in the concrete is then

E = I^2 * R * t = 18000^2 * 5 * 12E-6 = 19.44 kj

Now the average amateur tower base has about 2 cubic meters of concrete, or about 8E6 cubic centimeters, so the energy per cubic centimeter is 0.00243 joule per cubic centimeter. It takes 4.18 joules to raise the temperature of 1 cubic centimeter of water 1 degree Celsius. So we shouldn't expect the concrete to become perceptably warm to the touch from a lighting strike, and indeed it doesn't.

Of course there isn't a perfectly even distribution of current throughout the concrete. The current density is highest right at the surface of the rebar. A minimum Ufer must have 20 lineal feet of 1/2 inch rebar embedded in the concrete. That's a surface area of 2432 square centimeters. That gives us a current density at the surface of the rebar of 7.4 amps per square centimeter. That's surprisingly low isn't it? A good tower base or pier will use more than 20 lineal feet of rebar in its construction, reducing that current density even more. That's why it works.

Now if you only had a foot long J bolt embedded in the concrete, the current density would be much higher, about 150 amps per square centimeter, and then you could have problems with hot spotting. But that's not permitted by the NEC as a standalone ground, and since it isn't Code, your insurance doesn't have to pay off if your base cracks and the tower falls.

The procedure you outlined is often referred to as a 'load pull test'
and is commonly used to determine the source impedance of transformers,
generators, amplifiers and arbitrary networks, linear and nonlinear.

> Unfortunately, multiplying that series impedance by the square of the
> current through it often does not yield the true dissipation inside the
> generator. Why not?

Why should it?

A load pull test measures the rate of change of source voltage with
respect to changes in load current. It measures a source
characteristic, whose dimension happens to be ohms. The test does not
prove the existence of an actual series impedance causing an actual
voltage drop (and associated electric field) proportional to current
flow.

In order for power to be generated or dissipated, there must be both a
current flow and a potential (voltage drop) for that current to be
'pushed through'.

As Tom Donaly mentioned earlier, power production and dissipation is
associated with the divergence of the Poynting vector, E X H where E is
the electric field in (volts/meter) and H is the magnetic field
(amps/meter). 'X' is the vector cross product.

Unless the source impedance is a real, physical impedance (complex
permitted), there will not be a physical voltage drop associated with
it. Power generation or dissipation requires a current flowing through
a voltage drop.

Walt's book "Reflections" wasn't written for engineers, rather toward a ham radio hobby in which Walt clearly understood the need for easily understandable explanations for antenna and transmission line phenomena. Engineers and scientists don't need what he wrote, but a great many hams do. So he couched his comments in terms that they could much more easily understand. Rather than being a scientific treatise it was aimed directly at a populace of hobbyists who need the information but who for the most part certainly are not scientists nor engineers.

It is easy to understand why engineers and scientists would not subscribe to any technical publication wherein they find any hint of technical inaccuracy-even the use of a theorem that is well known to apply strictly to only theoretical cases. But within the world of ham radio seems to me that it must be viewed on balance as a greatly positive result in that many hams who have studied "Reflections" find their understanding of its subject material is greatly enhanced. And clearly not all professionals find a need to criticise the seemingly minor technical liberties taken in the name of simplification and ease of understanding by a ham radio populace most of whom don't have the advanced math skills necessary to analyze the underlying science.

If only Walt had thought to preface his use of the Conjugate Matching theorem with a mild disclaimer such as "While these remarks are not totally accurate from a purely scientific standpoint, here's essentially what happens..." he could have saved lots of bandwidth here and numerous trees from being pulped into paper to print all the protestations. I'd bet he would have, had he had any idea what the consequences of the omission would be. After all, he was writing to hams and I'm sure that he understands the science fully. Hopefully with the Worldradio edition some such disclaimer will be included. I'd hate to see this bru-haha go all over again.

Closed loop feedback systems can be wonderful things as long as the closed loop gain is well below the open loop gain of the amplifier, and the amplifier isn't overdriven such that it becomes voltage or current limited. That would appear to be the case for the IC730. It appears to be behaving like an ideal opamp.

I generally don't like ALC systems, since as often applied they produce amplitude distortion in what should be a linear amplifier system. (That's particularly harmful for digital modulations such as PSK31.) But if the feedback system is intelligently designed, it can linearize an amplifier system faced with a varying load. Intelligent design includes using a conservatively rated amplifier so that its rated output is well below the maximum possible output you could get from it if driven to the point of being voltage or current limited.

Ah, but the realm of the metaphysical is used to explain why a balanced
transmission line doesn't radiate. From the two sides of the line there
are two fields that (ideally) exactly cancel. So you can say the two
fields are still there even though they've cancelled each other.
It's analogous to the transformer case. If new hams have no trouble
accepting two fields cancelling, then why would they have any trouble
with two wave components cancelling?

Hi Dick,
I realize you're trying to justify why Reflections is the way it is. However, I absolutely disagree with the idea that ham radio publications should be dumbed down with inaccuracies in order that the typical ham can understand it. Difficult concepts can often be explained in a way that is technically accurate but that is easily understood by someone lacking an engineering background. 73,

I honestly believe that the purpose of all this is to draw attention to Chip, not to redress any kind of damage to him or Fractenna. It's succeeding in doing that as long as people respond. (And by this response I'm also guilty.)

As I told Chip in response to his email, there is no material on my site which is copyrighted by Fractenna. To date, no suit has been filed, and I'm not holding my breath. If one is filed, it should certainly be interesting to anyone interested in copyright law, to say nothing of students of psychology. In the meantime, the content of my web site remains unchanged, and I join the growing list of people who Chip has threatened to sue but hasn't.

So my request is to just ignore all the huffing and puffing, and not worry about it. It just plays into what I feel is the whole purpose of the exercise -- to draw attention to Chip. The more outrageous and bizarre the claims and threats, the more attention is drawn. I'm sure that this, rather than any sort of logic, is the reason for the level of claims and threats being put forth.

>It's even worse than that. Actually, the efficiency of a modern steam
>turbine electric power plant is about 30%. And they do push the theoretical
>limit pretty hard.

That's about right for a nuclear plant, because primary loop temperature is
kept relatively low.

(Thermal efficiency is relatively unimportant for a nuclear plant, of course,
because fuel costs are a negligible part of their bussbar power cost. Most of
the cost is debt service on the horrific capital costs incurred building them
in the US. Most of that is due to the average 12 years it takes to get a plant
licensed and producing power in the US. Racking up interest for that long before
generating the first billable kilowatt-hour makes the debt load huge. By contrast,
it takes less than 12 months in France, and less than 2 years in Japan to get
a plant licensed. That makes nuclear power much more economical in those
countries, France is now 86% nuclear and Japan is over 50% nuclear while
the US remains less than 6% nuclear.)

But coal, oil, and gas fired plants do have better thermal efficiencies than that.
More on the order of 38% for older coal fired plants. Combined cycle plants
have broken the 50% thermal efficiency barrier at the bussbar within the last
10 years, but they use an extremely high primary temperature. That puts rather
extreme requirements on the topping turbine loop (essentially a jet engine),
which makes them expensive to build and maintain. They also have to use
high quality fuel to avoid blade erosion in the primary loop. Few such plants
are in operation because their bussbar costs simply aren't competitive.

Of course by the time the power is transmitted to your home, it has encountered
a number of other losses. So thermal efficiency at the wall plug may be quite a bit
lower than at the power plant bussbar. If you charge batteries and run an electric
car, the total system efficiency begins to really reek, less than 6% end to end. A
conventional internal combustion engine in a car handily beats that, example a
Ford 351 Cleveland engine has a 28% thermal efficiency when operated at 80%

of torque peak, and a 13% overall efficiency on the EPA driving cycle test (designed to simulate typical driving conditions, though your mileage may vary). Diesels do better, as high as 45%, with typical numbers in the mid-30s.

Electric cars don't reduce pollution, calling them zero emissions is a non-sequitor. What they do is export pollution to a generating plant located elsewhere (the old not in my backyard syndrome), and at a lower total system efficiency so more fuel has to be burned than would be the case by simply using a combustion engine in the car. The power plant may have scrubbers that clean their exhaust of particulates and hydrocarbons better than the catalysts used on cars, but they can't scrub out the excess greenhouse gas (CO2) they have to produce due to the lower system efficiency.

OK, extreme topic drift there, but it is a pet peeve of mine that we are being misled about these things by certain supposedly environmentalist groups and the politicians who cater to them. I'm particularly irked by the Clinton/Gore people who signed the greenhouse treaty, yet are doing their best to prevent nuclear plants from being built and are pushing electric cars. That can do nothing except increase greenhouse gas generation, as well as making us more dependent on imported fossil fuels to fire the generators. (Clinton/Gore have pronounced domestic coal "too dirty", and are pushing for new power plants to be either natural gas or oil fired.)

Hi Dick,

Yes, I have a copy of his book, but it is not currently on my shelf because I've loaned it out. It is quite useful and well written. Absolutely everything above is correct and glowingly describes why he is so revered.

As for virtual shorts and opens - quite turgid. In fact the coverage of this topic has much too engineering to make an appeal to simplicity.

These recent postings emphasize the importance of defining the system when one speaks of efficiency. Considering the system to be Ed's house, the efficiency of his heater is 100%. The efficiency of the system consisting of power plant, distribution system, and Ed's house, as Gary points out, is more in the 30% range. If you consider the system input to be the sunlight used to grow the plants which became coal or natural gas, the efficiency is a whole lot less. Then beginning with the Sun's nuclear fuel. . .

>> What if RL is complex?
>
>Why make things more complex than necessary?

Making RL complex generalizes the problem, is certainly far closer to reality, and makes it simpler by discarding the false presumptions and artificial constraints to fit the special cases posed here. This perhaps is stealing the march on someone's presentation. And yet in the past 4 or 5 years I've yet to see this debate get halfway there (Zeno's paradox seems to be SOP).

They start being rather large at HF, though they are quite practical at UHF.
An 8 turn helix would need a boom about 16 meters long on 10m. It does have
good gain, and it naturally gives circular polarization, which might be beneficial
to deal with the spin modulation of Mode A satellites. I don't think there are any
new Mode A birds in the works, however, so that might be a moot point. Frankly,
I'd just build a quad or yagi instead. That'd be mechanically simpler, and linear
polarization isn't a detriment for skywave HF propagation.

Copper bolts would be best, because there's no dissimilar metals issue
at all. But good luck finding copper bolts. Copper is a bitch to thread, and
copper bolts aren't a production item. Naval bronze would be second best.
Marine suppliers should have these. (It is also the material from which
good clamps intended to go on ground rods are made.) It'll last many years.
Brass isn't a good choice. It will corrode quickly in this application. Stainless
steel will corrode in this application, but it does so slowly. Bolts made of 316L
will last several years if properly passivated (dipped in nitric acid after forming).
That's standard practice for marine hardware.

My point exactly - those steady-state conditions actually exist and
can be proven by measurements. They actually are what they are. You
would have us believe that there are invisible and undetectable
voltage and current waves flowing throughout the system with opposite
phases to each other. That's very close to the argument that people
use to try to prove that God exists.

> You need to look at the transient response
> to see what is really happening with wave reflections.

If you want to see how the steady-state condition evolved, then by
all means, study the transient buildup. But why does the average
ham need to bother himself with the transient buildup when the
basic principles of steady-state operation are so well known?

> I have no intension of turning this into an argument on points that I know
> to be so basic to understanding transmission line theory, so I will stop at
> this message.

Why? You would be predestined to win the argument if I were wrong.
Are you trying to tell us that you found holes in my steady-state
analysis and choose not to point them out? The basic problem with
your argument is that if it doesn't arrive at the known steady-state
conditions, it is worthless. If it does arrive at the known steady-
state conditions, there is no need for it (except as an academic
exercise in transient analysis). And I have pointed out a couple
of errors in your analysis. Please notice that neither you nor
anyone else is arguing with my steady-state voltage/current/power
numbers because all of them can be proven by measurement.

The way to cancel an unwanted voltage/current pair on a transmission
line is to supply another voltage/current pair with equal magnitudes
and of opposite phase. Once canceled down to nothingness, they cease
to exist. That's why there are no reflections on the coax going to
the generator and the forward power in the coax is exactly what
the generator is generating. Complimentary reflections from the
two impedance bumps have canceled each other out.

> with two wave components cancelling?

I don't have any trouble with two wave components canceling. In fact, that's exactly why there are no reflections on the coax looking into the Z0-match. Steve is saying they don't really cancel - that they continue to exist and are flowing down the coax even though it is impossible to measure them and their effects are undetectable. That's our bone of contention. He says they continue to exist after being canceled. I say they cease to exist after they've been canceled and that's why they cannot be measured and have no effect. There's a big difference between fields caused by currents in a wire canceling and the currents themselves canceling. In one case, the cause continues to exist. In the other, the cause ceases to exist.

Years ago, people were using reflections to "prove" that all transmitters re-reflect all of the incident reflections. That didn't make sense to me so I contacted Walt who freely admitted that he was talking about tube transmitters with built-in pi-net tuners that had achieved a match between the amplifier design load and the outside world. He expressly was not talking about fixed output solid-state transmitters which were just coming on the market when he first wrote the article. There are a number of similiar oversights in the first edition of "Reflections". Hopefully, most of them will be updated in the second edition.

Source record: 178857

Whoa! Hold on here for just a doggone moment!

I just received my QEX Sept 30, and didn't realize until now that this thread existed, which appears to be principally directed to the problem of conjugate matching.

I haven't read all of the posts, but from those I have read it is evident that those posters completely missed the point of my original Letter to the Editor. My point does not concern the conjugate match directly, only secondarily. The primary focus is to show that Steve Best's CommQuart article that assailed the entire basis of my book Reflections was based on an erroneous method of determining the output resistance of networks. The conjugate match comes into play only because Steve says it can't occur when a network has loss, and he makes this statement because he determined the network output resistance incorrectly. Obtaining the wrong value for the output resistance has led many otherwise knowledgeable people, including Steve, to make statements that are fundamentally untrue. This is the case in Steve's assailing Reflections. His statement that a lossy network cannot sustain a conjugate match is patently untrue. The following paragraph explains the basis prevalently used for obtaining the (erroneous) output resistance of a network, which is what Steve used in his CommQuart article.

It is fundamentally impossible to determine the correct output resistance of a non-symmetrical lossy network by measuring backward into the network. It is also impossible to determine the correct output resistance by calculating the transformation through the network if the same algorithm is used as in the backward measurement. Yet, many use this erroneous algorithm and backward measurement, deriving an erroneous answer without realizing it's erroneous.

I explained the reason for obtaining the wrong value of resistance in my original Letter to the Editor, and paraphrased it for emphasis in the Letter of Reply to Steve's, including the Rules for Transforming Impedances. Please re-read those two Letters. Steve's problem is in the incorrect use of attenuation. The problem is the same for lossy transmission lines, and it is easier to explain with lines. If one measures the impedance at the output of a transmission line, the line attenuation is being used in the wrong direction compared to that when the line is transferring energy from input to output. So let me demonstrate using a simple example of a 50-ohm half-wave line, attenuation 0.2 dB, and terminated in a resistive 100-ohm load. The SWR at the output is 2:1. With 0.2 dB positive attenuation the SWR at the input is 1.93:1 and the input resistance is 96.7 ohms. If we now start at the line input to calculate the output resistance, the correct answer must be 100 ohms. But let's see what happens if we attempt to measure the output resistance by looking back into the line from the output. We

terminate the line input with a 96.7-ohm resistor and measure the resistance at the output to be 93.6 ohms. Wrong answer! This is what Steve does, although it is obvious the correct answer is 100 ohms!

The reason for the error is that attenuation is positive during the backward measurement because the output is now a new input and the input is now a new output. When initially transforming from output to input, positive attenuation reduces the SWR and input resistance. Thus when calculating in the opposite direction, to determine the output resistance by transforming from the input resistance, NEGATIVE attenuation MUST be used to return to the values at the original starting point, the output resistance that actually exists, 100 ohms, not 93.6 ohms. This concept will become crystal clear if the calculation is performed on a Smith chart. As I stressed in my Letter to the Editor, Steve started out with a load impedance of 53.32 - j85.85 ohms and designed the network to match 50 ohms at the input. For this network to match the load, the output impedance must be 53.32 + j85.85 ohms. But then, not understanding that the true output impedance is 53.32 + j85.85 ohms, Steve attempted to determine the output impedance using the incorrect positive attenuation, obtaining the incorrect output impedance of 71.13 + j77.82 ohms. Because this incorrect impedance is not the conjugate of the load impedance Steve asserts incorrectly that no conjugate match can exist at the network output if the network has loss. This is the basis on which he assailed Reflections as presenting incorrect information. However, it is evident that when the network output impedance is the conjugate of the load impedance, a conjugate match does exist at the output.

Reflections 2, which is nearly ready for publication, discusses this problem in even greater detail.

I hope all posters will again review my Letters to the Editor to re-focus the thread back to the issue I originated.

I appreciate the confidence some of you have shown in my credibility, which has been tattered during this thread. Thanks also to all for your participation in this thread, it's a real learning experience.

Walt Maxwell, W2DU

It would be very nice if all engineers agreed on what constitutes
scientific knowledge. Given the history of the conjugate match
controversy between Warren Bruene and Walt Maxwell, and their
respective minions, one has to wonder if either side really
understands what it's talking about. Doing a crude, unscientific
survey of some of the old books lying around the house, I came
up with the following opinions written throughout the years by
various authors:
1. Power amplifiers should be terminated in a load
equalling Rp for the maximum transfer of power. This is from
Fred C. Jones book The Radio Handbook, circa 1936.
2. For maximum power transfer power amplifiers should be
terminated in a load equalling Rp. For maximum *undistorted*
power transfer they should be terminated in a load equalling
two or three times Rp. This from the text Electronic Communication,
by Robert L. Shrader, 1975.
3. No mention whatsoever of Rp in designing an amplifier, from
Care and Feeding of Power Grid Tubes by the laboratory staff of
EIMAC corporation.
4. Rp is a small-signal parameter, from The Radio Amateur's
Handbook, 1981.
5. Maximum power output is obtained when the load is the
complex conjugate of a dissipationless impedance Zs. John S. Belrose,
Walter Maxwell, and Charles T. Rauch writing in Comm Quart, Fall 1997.
6. Real amplifiers are terminated in an impedance about
five times Zs. Warren Bruene, responding to the above in Comm Quart
Spring 1998.

If people of the stature of Walt Maxwell and Warren Bruene can't
agree on what's right, what hope is there for the rest of us?

> Hi Dick,
> I realize you're trying to justify why Reflections is the way it is.

Bill, Walt Maxwell needs no justification from me. His lifetime of work, including "Reflectiosn", stands on its own. What I've given here is an analysis of the complaint against his book, distilled from much reading here and elsewhere. Finally, a couple days ago, it came out that the Conjugate Match theorm was useless outside theory, except for the little snippet that "Close" might be useful in describing matching. Problem was, Walt didn't mention that. Perhape he was distilling out everything uneeded to keep it basic for hams. I believe that was the case. If your mileage varies, well, I think I predicted it might.

> However, I absolutely disagree with the idea that ham radio publications
> should be dumbed down with inaccuracies in order that the typical ham
> can understand it.

As I mentioned in my earier post regarding the tuning of PI networks, inaccuracies are ubiquitous in ham radio, indeed in life itself. Fortunatley for most of us non-engineeers, close is almost always good enough. I'd imagine that in retrospect, Walt regrets ever borrowing the Conjugate Match theorm from the rest of you engineers for metaphorical use here, and especially so without so labelling it, as I mentioned.
If you think his doing so "dumbed down" ham radio you evidently never suffered much exposure to all the misinformation within the hobby that went before "Reflections", and is still way too predominant.
Mistakes are not unknown in engineering. I recall a new transmitter that fried a bank of receivers immediately when it first transmitted because it had in its design a tiny antenna change relay for the receiver bank that switched them on and off the transmit antenna line. The darn thing looked like it was designed for a 5 watt CB set, yet it had to isolate 3 KW of rf from the receivers on transmit mode, and it was way too tiny to do the job. I imagine the designer was thinking that since it didn't carry any voltage or power, only small signel reciever RF, why should it be any larger than necessary? Needless to say, that got redesigned posthaste.

> Difficult concepts can often be explained in a way
> that is technically accurate but that is easily understood by someone
> lacking an engineering background.

Bill, again, I know that engineers and scientists are, by nature and training, perfectionists, at least to a high degree, and your attitude here seems to demonstrate that. I certainly have no argument with you on your own level, but on my own it's a different matter. The difference is that Walt did it while everyone else is mostly just talking about it.
And criticising the few possible areas in his work where criticism is possible.

Many of us didn't get a good opportunituy to get a good math background. I attended a tiny high school where Trig, if you could even get into that

class, was considerered "advanced math". Most of us who played any sports didn't even get trig since the SINGLE class, with a single math teacher in the school, was held at the same class period when sports practice took place. So most of the math I learned was learned on my own and has been limited. I got no engineering degree, but that hasn't kept me from a 35 year career in the technical part of radio. I've had some pretty heavy duty electronic hardware completely disassembled, scattered all over the floor, and got it back together, problem solved and working right, on quite a number of occasions. To many hams including myself, antenna and feedline theory have been among the most obscure of radio subjects. Walt has helped considerably to illuminate the subject, and I have no qualms whatever in defending his excellent effort.

Did Walt make a mistake in using the Conjugate Match theorm as he did? Not from my point of view, now that I know that it's a theoretical concept only, evidently used mostly as a proof of systems. I confess I was wondering what the flap was all about when the criticism first surfaced, but decided to stay with it until the entire story came clear. I'm glad I did.

As Professer Mac Maclaughlin, former student of John Kraus, said earlier in this thread, "With hand grenades and antenna matching, close is good enough!" That's sufficient for amateur work and most -indeed nearly all- professional radio work too. And as far as I'm concerned, for a metaphorical use of the Conjugate Matching Theorem. If it's good enough for Walt Maxwell it's certainly good enough for me. James Clerk Maxwell won't know the difference.

73, Dick W0EX

Thanks for the replies.....

I asked the same question on the electrical engineering newsgroup and was told to get Silicon Bronze bolts. You can picture the blank look on the stock boy's face when I asked for some of these at Home Depot. A web search for them turned up lots and lots of wholesale distributors for silicon bronze bolts, but they all failed to mention where Joe Public can actually purchase them. :-) Maybe I'll find them at an electrical contractors outlet.

I'll use the stainless steel one for the time being until I can find the kind I really need. I've never really tried making a good ground system until now. I'd usually just put a couple of rods at the base of the tower and pray. After reading about lightning on the Polyphaser website I've got a much better handle on what to do. And since I live in Florida it's pretty important to do it right. I don't want to lose my ham gear -or- my house!

>

To All Readers:

It has come to my attention that Roy Lewallen, W7EL, has posted an unauthorized copyrighted file on his

http://www.eznec.com

web site.

The file is of a fractal antenna, commonly dubbed 'MI2' . The copyright holder of this material is Fractal Antenna Systems, Inc., which has not been ask for , nor has granted, publication and distribution of this file by Mr. Lewallen.

The file was transcribed by Steven Best and thus is a derivative work of the aforementioned copyright material, in which the copyrighted material is at least substantially recognizable in Best's rendition.

It has been initially assumed that Mr. Lewallen was not aware of the copyright infringement, however in private correspondence he has chosen to deny that such copyright protection exists.

Mr. Lewallen is being formally sent a letter requesting that he cease and desist the further distribution of this copyright material and will have until

December 15, 2000 to comply. Failure to do so will lead to suit against Roy Lewallen d/b/a Lewallen consulting/EZNEC.

Those who have downloaded this file are so advised that this is copyrighted material with an intended controlled distribution; it is not in the public domain; its web-based distribution does not constitute 'fair use'.

Copies of the file are available--under held copyright--by request, to those members of the fractal antenna reflector:

fractalantenna-subscribe@egroups.com

In a few weeks, it will also be available as a conditional(licensed)download from the web site

http://www.fractenna.com

Readers are advised not to break copyright law by downloading said file from the EZNEC web site.

Thank you for your help and understanding.

Sincerely,

Nathan Cohen, Ph.D.
CTO

>From: Richard Clark

>>Over the years, I have noted that most who say this have not made such
>>voluntary contributions personally. :-)

>Consult the contributor's listing at the site:
>http://www.qsl.net/donations.html

Actually, the implication of your original post was that ARRL should emulate the qsl.net mo and operate on donations. I wonder if you have, since your membership expired, made such donation to ARRL personally?

So I went to qsl.net and entered a few searches. My first was RFI. The first valid page it sent me to was:

http://www.qsl.net/arrlsw

It then linked me (after a really cryptic search) to:

http://www.qsl.net/tvi/index.html

This page was "under construction" a year ago, and, unfortunately, the very excellent project really didn't get much support. The "publications" link sent me to:

http://www.arrl.org/

Compare this to ARRL's RFI information at:

http://www.arrl.org/tis/info/rfigen.html

The above is the third link off of the qsl.net RFI site.

The filters link brought me only to K1UHF's filters, excellent filters, but there are a lot more filters available. See http://www.arrl.org/tis/tisfind.html and scroll down to the filters listing.

I then compared the results of "education" to the into at http://www.arrl.org/ead.

I offer these contrasts because it is one that I am most familiar with, but it also illustrates a point; QSL.NET and ARRL are apples and oranges. I think they have done an excellent job of putting together a site that allows hams and clubs to post pages of information to share with others -- a very laudable goal. As their page says, qsl.net is funded by a combination of banner ad revenues, contributions and non-free services (member only? :-)). That funding can just about fund the web page -- unlike ARRL, they do not fund staff working on various educational, technical and regulatory projects. This weekend, I am doing some testing of the radiation potential of home electrical wiring,

determining whether a signal level of -80 dBm/Hz has much interference potential for ham radio. This is in response to a request from the HomePlug industry group. Next week, I am off to Phoenix to do some field testing to determine the interference potential from the VDSL system installed in Phoenix, then off to L.A. to meet with an industry representative about Ultra Wide Band technology.

>And - yes - I once was an ARRL card carrying member. Pity this fallen
>sinner.

It is unfortunate that ARRL and amateur radio lost this support. Every year, at budget time, I have to plan what I can, and cannot do, next year. I would love to attend the EMC Symposium next year, and go to a few more industry meetings and industry conferences. But the reality is that the funds are limited. If you feel that volunteerism is important, would you care to fund one of the trips?

Now, considering all of this response from two people, is this a case of no good deed going unpunished? I did feel that posting the site where some could download the tuner article would be helpful. I do realize that ARRL offers its product reviews on the members-only site, but it also offers over 500 technical articles for free download on the pages at http://www.arrl.org/tis. Perhaps you could volunteer yourself over that way for a more balanced view. :-)

84. Tuning Elevated Radials?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-01 00:00:00 UTC
From: Herb Rosenberg <kg6ok@pacbell.net>
Message-ID: <39D79EFE.91FADF18@pacbell.net>
Source record: 178867

I have just set up a shunt feed for my tower, with 4 elevated radials at about 8-10 high.

I cut the radials at about 70 feet each, and put them in place. I then used an MFJ 259 with a pair of opposite oriented radials made into a dipole (disconnected from the tower of course), to measure the resonance point, with the hope that I could use this to trim the radials. I was told that this was a good approach to doing this.

Well, the MFJ 259 shows the resonance freq of each pair of radials at about 2.300 MHZ. The best dip I get there is about 2:1 swr. If the radials are 70 feet each, I would have expected the resonance to be much higher, and I don't want to start cutting the radials as aggressively as they measurements would suggest.

Any help or ideas would appreciated.

Thanks.

Cecil: I started to check the example. I think the input impedance to the
1/4 WL line is 1748 ohms (approx) not 51.5 ohms. I think the section of 300
ohm line should be 1/2 WL long.

Boy, I'm sure confused. I always understood that the wattage dissapated across the plate resistance caused a bit part of that heat in the PA cavity. It sure doesn't come from the filament alone.

Can someone tell me which dissimilar metals will corrode when they are in contact with each other? I'm using a solid copper gounding bar as a single point ground bulkhead for my tower and station equipment on the exterior wall of my house. I have ten 8' grounding rods surronding the tower and bonded together with the #2 copper wire which runs back to the bulkhead. I've got some large copper connectors to use with the #2 wire but what type of metal bolts can I use to attach the copper connectors to the copper bar? I looked everywhere for brass, bronze or copper bolts with no luck. Would stainless steel work? I just don't want to start corrosion using the wrong thing.

Thanks for some advice,
David, K4ZZR

In the case of the re-reflected voltage at the match point, it adds to the driving voltage and the above formula is correct.

I may be wrong but I assume your statements above to be similar to feeding a coax with two 100 watts sources in parallel. Neglected the affects of the two source impedances , the voltages are combined in parallel. This is a different situation than we are discussing.

Steve

The law of conservation of energy demands that the total power dissipated in the transmission line system be equal to the power delivered by the source. From the steady state conditions, we know this to be true. We deliver 100 watts of power, 100 watts of power is dissipated in the load. Transmission line theory and circuit theory requires that we establish the correct relationships between voltage, current and power.

In my next post I will discuss the current and voltage.

Steve

Cecil:

In the example that you describe above, we know the following as fact. The forward power in the 51.5 ohm coax is 100 watts. The reflected power in the 51.5 ohm coax is 0 watts. The forward power in the 300 ohm line is 200 watts and the reflected power in the 300 ohm line is 100 watts.

The law of conservation of energy is satisfied because 100 watts is delivered to the system and 100 watts is dissipated in the load. Now we need to establish the correct relationships between voltage, current and power at the match point.

Looking at only the steady state power levels, most people would immediately conclude (really assume) that the 200 watts of forward power in the 300 ohm coax is a result of the 100 watts of reflected power adding to the 100 watts of source power, end of story. The only thing needed to make this all work is a total re-reflection of power at the match point. Believing our conclusion to be correct, we can easily manipulate the math to make it all work out.

Now, here's the two major problems:

1) 100 watts of forward power added in-phase with 100 watts of forward power does not equal 200 watts of forward power. In the 300 ohm line, 100

watts of forward power has a voltage magnitude of 173.2 volts. 200 watts of forward power has a voltage magnitude of 244.95 volts. So, for 100 watts + 100 watts to equal 200 watts, 173.2 volts + 173.2 volts would have to equal 244.95 volts. This math does not work. Multiple forward powers in a transmission line add as previously described.

2) Transmission line theory demands that the level of power reflection at *any* impedance junction be a function of the impedance discontinuity at the junction. In this example, we have an impedance discontinuity between a 51.5 ohm line and a 300 ohm line. Transmission line theory tells us that a total reflection of power cannot occur at this junction.

Now, let's look at the wave mechanics to see if we can determine the steady state power levels and satisfy issues 1 and 2 above.

First, does the generator really deliver 100 watts of forward power into the 300 ohm transmission line? the 100 watts of forward power in the 51.5 ohm line arrives at the 300 ohm line and sees a 300 ohm impedance. The reflection coefficient at this junction is +0.707. There must be some power reflected at this junction and some power transmitted into the 300 ohm line. The level of reflected power is 50 watts and the level of power transmitted into the 300 ohm line is 50 watts (rounded values). So, the correct source power delivered into the 300 ohm line is 50 watts not 100 watts.

Now, through a series of wave reflections between the load and the match point, the steady state levels of forward and reflected power in the 300 ohm line will develop. Let's now jump to the steady state. The level of reflected power in the 300 ohm line is 100 watts. This 100 watts of power arrives at the input to the 300 ohm line and sees a 51.5 impedance. The reflection coefficient is -0.707. The re-reflected power is 50 watts and the power transmitted into the 51.5 ohm line is 50 watts. So, the correct re-reflected power in the 300 ohm line is 50 watts not 100 watts.

The 200 watts of total forward power in the 300 ohm line is a result of 50 watts adding in phase to 50 watts. From the formula presented earlier:

Ptotal = P1 + P2 + 2 sqrt(P1) sqrt(P2) = 50 + 50 + 100 = 200 watts. Correct addition of in-phase power.

Now, let's look at the problem from the voltage and current perspective. From the steady state conditions, we know that the total forward voltage in the 300 ohm line is 244.95 volts and the total forward current is .816 amps. The source power delivered to the 300 ohm line is 50 watts. The forward source voltage and current in the 300 ohm line are 122.47 volts and .408 amps. The level of reflected power arriving at the match point is 100 watts and therefore, the reflected voltage is 173.2 volts and the reflected current is 0.577 amps. Looking at the wave reflection analysis in detail, the phase of the reflected voltage and current arriving at the match point are 180 degrees out of phase with the forward source voltage and current at the match point. As a result of the -.707 reflection coefficient at the match point for the reflected wave, the reflected voltage is 122.47 volts and the reflected current is 0.408 amps. This reflected voltage and current

add to the source voltage and current and the total forward voltage and current are 244.95 volts and .816 amps. This is 200 watts of total forward power.

Now, the impedance match. How does it occur? At the match point, there was a 50 watt reflection of source power. When the 100 watts of reflected power arrives at the match point, it transmitted 50 watts of power back into the 51.5 ohm line. These two powers are 180 degrees out of phase. As a result, the total rearward voltage and current at the match point become 0 and no reflected wave exists (wave cancellation).

73,
Steve

Aside: There are two mathematical methods used with reflection coefficients. In one, the reflected voltage is equal to the incident voltage * +rho and the reflected current is equal to the incident current * -rho. In the other convention the reflected voltage is equal to the incident voltage * +rho and the reflected current is equal to the incident current * +rho. Both can be correctly used so long as the math is consistent throughout the analysis. For example, in one, the total current at any point on the line is Itotal = Iforward + Ireflected and in the other it is Itotal = Iforward - Ireflected. I mention this because I think Cecil and I use different methods.

Even if there were grounds for this frivolous suit, the
practical aspects of this suit are quite interesting.

1) What court will have jurisdiction?, and how will it
be determined?
For example, a court in a given state has jurisdiction only if both
plaintiff
and defendant are residents or have a "link" to that state. How will fracky
serve the suit?

2) What are the damages? Fracky has NO revenue based upon the
design in contention and no way of establishing damages for said claim.

3) He is a pompous ass and when in front of a judge acting as his own
attorney as he has been doing all along, well, folks guess what....said
judge will figure it out just as we all have...see #4

4) No attorney will take this on given the DOCUMENTED history
of fracky's BS on this NG.(Exhibit #1). Fracky has not only shot
himself in the foot but has shot both feet off and is up to his belly
button. (The meat grinder is not needed)

5) Fracky is inept with the English language and in conveying a
coherent thought, even if he had one.

Hope this helps
73,
Chuck...

This suit will never happen. It will cost fracky too much $$$
to even figure out how to do it, (if he can even find an attorney,
actually, 2 attorneys to cover both states, that will rep him after
all the crap he has put on this NG).

hope this helps even more...

I'm no HF mobile guru myself but despite the obvious inefficieny of the Hustlers
a clubmate of mine n2ss has worked well over 200 countries with a 706 and
Hustlers poking up from the trunk deck of his sedan. An SUV center-roof and
quick-disconnect installation should work even better. There are a lot of
"realtives" in these kinds of laborious discussions and quite often operator
skill, propogation and dumb luck prove to be more important factors than a dB or
two or three difference in antenna efficiencies.

Unless you are extemely restricted for space you would be much bettter off using a simple 1/4 wave ground plane or 1/2 wave dipole. A 15m GP would be only 11.1 feet tall. A 10m version would be just 8.3 feet tall, etc., dipoles would be twice those lengths long and would be far more effective than a Slinky antenna.

David,
Use the stainless steel bolts for corrosion resistance. Don't
worry about the dissimular metal thing, it isn't worth it on a
ground system.

Branched Erect Ether Radiator, Cyclic Antenna Node
Published by: Ima Hogg, Ph. D, and Watt S. Updoc, MFIC
Upper East Tennessee Polyester Technical Research Institute

Our research into the Branched Erect Ether Radiator, Cyclic Antenna Node antenna (abbreviated BEERCAN) was initiated in response to this letter received at the Upper East Tennessee Polyester Technical Research Institute in early March 2000. I quote:

"Me and J. B. was wondering what we was gonna do with all them luminum cylinders piled up in the front yard of the trailer now that the recyclers done quit paying a quarter a pound for them. J. B. observed that luminum is a conductor of lectricity and, being as lectric is the same as radio, he figgered that luminum would carry radio.

"Now, J. B. comes up with stuff lack that when he's been coon huntin all night cause he never goes coon huntin without he has a mason jar full of homebrew. Only this time he had got some bad stuff; I reckon him and Leon had run it through that old Camaro radiator and it was plumb full of lead. I keep tellin J. B. that he's gonna get the lead poisonin from filtering homebrew through that radiator but he says that 69 Camaro was the best car he ever owned and he was gonna keep usin that radiator to condense his homebrew. I reckon his mind's gone.

"So, anyway, J. B. continued to look at them luminum cylinders and look at the ol busted up CB antenna that was laying down across the Camaro that was sittin in the side yard of the trailer where he had parked it when the engine blowed up in 1975.

"Reckon how we'd hook them things up so they'd be long enough to make a antenna, says J. B.

"J. B. , says I, they ain't no way you gonna turn them things into no antenna.

"Well, that was the wrong thing to say cause J. B. figgered I had done challenged him and he was bound and determined to build a antenna with them luminum cylinders. . . .

If you drive thru Conejos county Colorado which is south of
Alamosa you will see several structures with stacked ~25 element
horizontally polarized yagis of a size for the cell band. This
area is very sparsely populated. I asked the proprietor of the
ranch where we stayed and he said they were for phone service
since USWest (now QWest) couldn't deliver standard phone service
and the cell tower was >15 miles distant. I'm sure these antennas
were legal. Just FYI. I don't know what gain you would get such
an antenna but 18 to 20dBd would seem about right.

Hey David, I just had a thought. You have any starter generator rebuilders
in your area? If so, see if they have any copper bolts, like what comes out
of the end of a solenoid. I had to replace on in the starter of a Case skid
steer loader the other day. If you can't find anything, email me direct &
I'll check back with the place I got my copper bolt.

Unfortunately, there is a wide gap between pure physics and RF
engineering. In RF engineering and power engineering the mere
movement of electrical energy past a point is defined as power
with no work required. And the Power Flow Vector is defined at
a boundary.

It's been my experience that a beam will in most cases be of more
benifit than a vertical is. A beam, with it's nulls, gives you a way
to 'get rid' of' strong signals. Can't do that with a vertical.

There's nothing magic about 50 ohm coax. Years ago, most hams didn't
even own an SWR meter and just dipped and loaded their finals into
75 ohm coax if it were available. Since a dipole in free space is
a good match for 75 ohm line, many hams used 75 ohm coax in the 50s.
Even into a 50 ohm load, 75 ohm hardline with an SWR of 1.5:1 is
usually less lossy than ordinary 50 ohm coax. Go for it.

Actually, Jim, I have posted a considerable amount of data on this NG. Sometime back I realized that this was to no end , and instead placed it on the web pages at

http://www.fractenna.com

This, of course, after publication through the years.

Could you please state what is it you wanted to know? If it doesn't exist in some form that is available on the 'net, then I will be happy to put it up there.

But it's difficult to be net control with a beam. That's why I asked
him what he wanted his antenna to do.

There is no ambiguity in what I said or what I did.

The JST-245 certainly will NOT put out (only) 1/2 watt TX (well, maybe on RX audio:-)), and has to be stepped down for QRPP work.

Hi Walt:

I have not been reading every post to this thread but I think it is important for everyone to understand that there is no effort here to tarnish the reputation of anyone. Period. I respect Walter very much and think that there is a tremendous amount of information in Walter's book that has great value to the amateur radio community. When the second edition is published, I will gladly put my money on the table for a copy.

There are topics in Walter's book where I would not even begin to argue with him because in these areas Walt simply knows more than I. No arguement on my part.

In the area of impedance matching and the conjugate match we disagree. In any technical field people will disagree with one another. As long as the discussion can stay at that level we all should be fine with it and we all should hope to learn something.

More below ..

>

I believe Walter is misinterpreting my methods of calculation.

In the above example, we have a 50 ohm 1/2 wave line with a total
attenuation of 0.2 dB, terminated with a 100 ohm resistor.

If we connect an analyzer to the input of the line, we will measure an
impedance of 96.7 ohms. This is the input impedance to the line.

Now, from here what are we trying to determine?

1) Knowing the input impedance to the line, we can determine the load
impedance at the output end of the line doing a reverse impedance
calculation with the "attenuation" and "phase" of the line reversed.
Starting with the input impedance of 96.7 ohms, we would find the load
impedance to be 100 ohms. (see my letter for the exact formula)

2) Now we want to determine the "output impedance" at the load end of the
line. This is not the same as the load impedance connected at the end of
the line. How do we do this, we connect an analyzer to the output end of
the line and measure the impedance looking in the rearward direction. The
result of this measurement (or calculation) will depend on the impedance
terminating the input end of the line looking in the rearward direction.
This "terminating" impedance IS NOT the input impedance of the line. Unless
the input end of the line is connected to something, the terminating
impedance will be an open circuit. (Again, see my letter)

> impedance, a conjugate match does exist at the output.
>

As I have said, the output impedance of a network is not the same as the impedance connected at the network output.

In the discussion above, Walt simply states that I am wrong because he believes that the output impedance is the conjugate of the load impedance, therefore I must be wrong. Rather than simply stating this position I think it would be valuable for everyone to see the details of our calculations.

At this point, I would respectfully ask Walt to take the network as described in my example and detail the calculations he uses (step by step) to determine that the output impedance is the conjugate of the load impedance.

I will respond in kind and everyone can see how our calculations differ.

Hi Ed--

There's no question League reviews carry an especially high onus of accountability. For that reason alone, I think it extremely important for technical tests to be conducted in-house, at the Lab, by Lab staffers. Some tasks just shouldn't be "outsourced" out of fairness to the manufacturers and advertisers whose products may be mis-represented.

Now, if we could only convince the Editor to include a box or sidebar in the Review section for reporting test erata from the previous issue....

Source record: 178676

I purchased a Mosely RV-6-WARC Vertical antenna in May. Reports I have received are from very strong to weak depending on the distance. The antenna is installed at ground level. It is mounted to a 2" pipe, 4 ft in the ground the antenna is about 8" above ground and grounded to a 8" ground stake. I attached a counterpoise on 10 M, 12, 17 and 40 meters, (not grounded). The antenna is approx 100" from any building in a pasture, with dry sandy soil, it hasn"t rained about 50 days. The transmission line is approx 125" of RG213 coax. The SWR on 15 meters is>3.5, the rest are between 1.7 and >2.5 which is not close to the spec"s Mosley claims. I can tune it with my TS440/AT so I"m not worried about hurting my rig. The shack is on the second floor of my house and I don"t get any RF in the shack. I have not been able to get any help from Mosely, called three times and the engineer was to busy to talk, and I also sent him a complete run down of the setup in July with a SASE still no response. I thought of changing the length of the coax, or raising the antenna up to about 10" in the air and putting down about 8 to 16 " wave radials, I don"t want to waste my time or money if this won"t help. All help would be appreciated. Chip N1IR, please do not respond to this post.

changes.

This transformation is determined through the reflection coefficient. The total voltage reflected at an impedance discontinuity is equal to the incident voltage times the reflection coefficient. The total voltage transmitted through the impedance discontinuity is equal to the incident voltage + the reflected voltage. Simple transmission line theory.

>
> For 100 watts into 51.5 ohms plus 100 watts into 300 ohms to equal 200
watts

WONDERS,
> it does exactly that. 71^2/50=100 173^2/300=100 244^2/300=200
> 71+173=244 Funny how that works.

This is a misinterpretation of the steady state conditions. You are looking at the *total* voltages in the steady state, not the individual components that make up the total. You forgot to take into account the impedance discontinuity at the junction.

+71.8 v in the 51.5 ohm line (100 watts) arrives at the 300 ohm line and sees an impedance discontinuity. As a result, a voltage reflection occurs. The reflection coefficient is 0.707. The reflected voltage is equal to +50.7 volts (50 watts reflected in the 51.5 ohm line). The total voltage transmitted into the 300 ohm line is equal to +122.5 volts (50 watts on a 300 ohm line).

Continuing, we know that the reflected voltage arriving at the impedance junction is equal to -173.2 volts (100 watts in a 300 ohm line). It too sees the impedance discontinuity. The reflection coefficient in this direction is -0.707. The re-reflected voltage at the junction is +122.5 volts (50 watts in a 300 ohm line). As a result, the total forward voltage in the 300 ohm line is 245 volts, which is the total 200 watts of *total* steady state forward power. The rearward voltage transmitted back into the 51.5 ohm line is equal to -50.7 volts (50 watts ina a 51.5 ohm line). This rearward voltage adds to the original reflected voltage (+50.7 volts) and

the two cancel to a net *total* rearward voltage of 0 volts. Hence, no rearward traveling wave past the match point - the steady state match.

The impedance discontinuity between the 51.5 and 300 ohm lines never changes. The effective steady state line or input impedance at that point is 51.5 ohms only because the rearward voltages cancel each other leaving a total voltage at that point equal to 71.8 volts:

Total voltage at match point = (forward V in 51.5 ohm line + reflected V in 51.5 ohm line) + (reflected V in 300 ohm line + re-reflected V in 300 ohm line) = (71.8 + 50.7) + (-173.2 + 122.5) = 71.8 v

Total current is found in a similar manner. The total impedance (line impedance) is simply Vtotal/Itotal which, in this case, equates to 51.5 ohms at the match point. Again, a steady state condition. Funny how transmission line theory and circuit theory work.

The issue is simply technical truth. The truth is that a total re-reflection of power does not occur at the match point. Why not just explain it correctly instead of using a model that does not represent the physics of what is truly happening in the system?

> > So, the correct source

>
> Nope it's not because we can measure otherwise. You cannot
> source 50 watts and get 100 watts to the load. Are you really
> pulling our legs with all this perpetual motion stuff?
>

Again, you are only measuring the *total* forward power not the individual components.

Perpetual motion??? How about circuit theory. 122.474 volts (50 watts in a 300 ohm line) adds to another 122.474 volts (50 watts in a 300 ohm line) resulting in a total voltage of 244.94 volts (200 watts in a 300 ohm line). In any impedance, if the voltage doubles, the power goes up by a factor of 4. This is not perpetual motion, it is simple circuit theory.

> Don't you understand that the phasor addition of two voltages can result in zero
> voltage and the phasor addition of two currents can result in zero
> current? There is zero reflected voltage and zero reflected current on
> the coax after steady-state conditions are reached.
>

Funny, but this is exactly what I said in my post:

"Now, the impedance match. How does it occur? At the match point, there was
a 50 watt reflection of source power. When the 100 watts of reflected power arrives at the match point, it transmitted 50 watts of power back into the 51.5 ohm line. These two powers are 180 degrees out of phase. As a result, the total rearward voltage and current at the match point become 0 and no

reflected wave exists (wave cancellation)."

> use to try to prove that God exists.

Hi Cecil:

We both agree on the steady state conditions. They are measurable and they are fact. Knowing these steady state conditions we know only the following:

1) The *total* forward power traveling in the 300 ohm line. It is 200 watts.

2) The *total* rearward power traveling in the 300 ohm line. It is 100 watts.

3) The *total* forward power traveling in the 51.5 ohm line. It is 100 watts

4) The *total* rearward power traveling in the 51.5 ohm line. It is 0 watts.

With these measurements alone, we know nothing of the true source power delivered to the 300 ohm line (more on this shortly) and we know nothing of the re-reflected power at the 300 ohm line input. Any other assumptions at this point are meaningless.

>

The average ham does not need to bother himself with any of this. The real question is do you, I and other interested parties want to understand wave behavior. It is an academic exercise but one that many enjoy discussing.

The steady state conditions are well known but they are a result of the transient behavior of the system. Some of the conclusions drawn from only looking at the steady state conditions are incorrect and do not correctly describe the behavior of wave reflections in the system.

> Why? You would be predestined to win the argument if I were wrong.

> anyone else is arguing with my steady-state voltage/current/power
> numbers because all of them can be proven by measurement.

First, you may want to check my response to your previous post.

Second, my transient analysis does arrive at the correct steady state conditions. Third, (IMHO) it has value because it correctly describes the behavior of wave reflections at the match point. Note that I can not claim my transient analysis as original. It is clearly described in several texts but these works have been misinterpreted.

I will agree with you that your description of the steady state condition is correct as it relates to the forward and rearward traveling power in each line. Where I disagree is in your description relating these forward and rearward traveling powers to the wave reflections at the match point.

>
> The way to cancel an unwanted voltage/current pair on a transmission

> to exist. That's why there are no reflections on the coax going to
> the generator and the forward power in the coax is exactly what
> the generator is generating. Complimentary reflections from the
> two impedance bumps have canceled each other out.
> --

This is correct and *exactly* what I said in my previous post. This is how the impedance match works. Given that you understand wave cancellation I don't understand why you insist that a total re-reflection of power is required to describe the impedance match? These are contradictory positions. If a total power re-reflection occurs, no power is available for wave cancellation.

Back to the example:

I tried to think of a simple way to come to agreement on the true source power delivered into the 300 ohm line (I.e. 50 watts rather than the 100 watts). What I came up with is this.

Assume that the 300 ohm line is infinitely long so that no reflections from the 51.5 ohm load ever make it back to the match point. What is the source power delivered to the 300 ohm line? It is 50 watts, not 100 watts.
Now make the line 1/2 WL. The only thing that has changed is that reflections arrive back at the match point from the load. Re-reflections occur at the match point and in the transition to the steady state, the total forward power changes from 50 watts to 200 watts.

I have to apply a correction.

The ALC on my rig (and very likely Roy's and Cecil's) tries to keeps the forward VOLTS constant versus changes in load impedance - not constant forward power.

It is impossible for the ALC to keep the forward power constant under varying load conditions.

In any case, what we might like to see is OUTPUT power into the load for a varying load but that can be accomplished only by human intervention. And if intervention is to occur obviously it would be better to intervene in the tuner.

Furthermore it involves large variations in efficiency. But this should not worry anybody unduly because in order to obtain a constant load power it is necesssary for the experimenter to accept that the PA has to be set to underperform even when the load is at its optimum design value and swr is 1:1.

That changes in load angle will have an entirely different effect on load power from changes in load magnitude, even for the same shift in swr, appears to have been overlooked.

Thank heavens control of PA drive changes over to reflected volts before the PA blows up.

This illustrates the difficulty inherent in trying to explain
something like a quarter wave transformer by keeping track of
the incident and reflected voltage and current waves. Such an
approach leads to concepts such as two waves traveling through
a transmission line which, if 180 degrees out of phase with one
another, carry no energy; have no momentum; create no fields;
don't reflect; don't refract; have no photons;
and, because of the above, are
totally undetectable. This is only one difficulty. There is
also the problem of how this produces what amounts to a virtual
check-valve for energy, and the question of how the energy that
is originally reflected from the plane of intersection of the
two transmission lines has its direction reversed, and how it is
carried to the load. Perhaps the geniuses on the electromagnetics
newsgroup can decipher all this; I can't.

Fortunately, there's another explanation that only
relies on one's ability to believe that a quarter wave piece of
transmission line transforms its terminating impedance by Zo^2/Zl.
Anyone can look in any book on transmission lines, and, in a couple of

minutes,
find out how transmission line transformers work in terms of impedance transformation. This sure beats trying to understand a reflection analysis, and, it's just as valid, because all the assumptions are derivable from Maxwell's equations.

Can you cite any issue for which such errata would be required? It remains to be seen as to whether an errata is needed for the tuner review, but, to date, the number of Feedbacks on the test results has been very small. Not one has been required due to a testing error in the ARRL Lab -- they was a mixup of graphs once, a typo and some other error that the Lab should have caught on the Finals.

If you can offer anything specific that you believe to have been an error, please let me know.

You may want to try Radio Shack part number 15-1843.

It is on sale now for $12.99. If this particular one doesn't work,
they have several others. Many of the indoor TV antennas also work
with FM. Just ask the salesperson to help you with your needs.

Hi Ed,

Frank miscalibrated the SWR meter he used during his tests. I have a
letter here somewhere to that effect. Frank felt it should have been
corrected.

Also, there should have been some mention of the sensitivity of the
measurements and how they affect the measured values.

I can site an example of an AL-1200 amplifier that was tested, and how
the ARRL power source was bad in the lab was bad. The ARRL never
corrected that error, and the even published the bad data despite the
fact I pre-warned tem they there was a problem somewhere in their
supply system.

Also the IMD measurements on an AL-800H first came out many dB better
than I measured here, then they came out worse, then I checked the PA
here it it came out the same as all other 800H PA's which are back
with the first measurements.

Let's face it Ed, you guys are like anyone else. Your measurements are
never perfect.

The problem isn't with making an error, we all do that. The problem is
in never correcting the error.

As the impdance of my antenna changed from 1:1 to 3:1, the forward power changed only about 2%. The magnitude of the impedance had to have changed much more than this. So I don't believe this is correct.
>
> It is impossible for the ALC to keep the forward power

Why is that? In my homebrew rig I have a simple Bruene-type directional coupler monitoring the forward power. I detect its output and use it to control the drive to the final stage. Works fine. Without looking at the schematic, I'd guess that the ICOM uses the same method.

Of course, this only works over a limited range of SWR.

When I get a chance I'll check the efficiency of my homebrew rig when driving various loads. My feeling is that it doesn't change a great deal up to an SWR of 2 or 3:1 or so, but I might be wrong. It has a class C output stage, though, so will behave differently than the Icom.

How about if the 15 watts is being dissipated in a resistive load
attached to a circulator as in a signal generator. Is the generator
still generating 85 watts?

It's really not hard to do with feedback. My power supply has an output impedance of very nearly zero, as does my stereo. It's even possible to create a negative output impedance, although the result is generally undesirable.

A real world zero ohm output impedance amplifier can still operate properly into a limited range of impedances, however.

My rig puts out 100 watts forward and 15 watts reverse, resulting in 85 watts at the load. The cable loss is negligible. If the rig's not putting out 85 watts, how much is it putting out? And where's the difference between this amount and the 85 watts in the load going?

If you want to dissipate 85 watts in a load and 15 in a circulator, well, then, you'd better put out 100 watts. Move the circulator into the rig, and, voila! the rig is putting out 85 watts again.

The laws/rules governing wave behavior are pretty well understood and
we usually simplify the equations as much as possible by dropping
terms that cancel or are negligible.

We do that with Maxwell's equations. We have one simplified
set that works for small loops and another simplified set that works
for large loops. Should we not simplify by dropping out the negligible
terms? Should we always work with the full set of equations?

> The steady state conditions are well known but they are a result of the
> transient behavior of the system. Some of the conclusions drawn from only
> looking at the steady state conditions are incorrect and do not correctly
> describe the behavior of wave reflections in the system.

There are not many conclusions to be drawn. Every steady-state parameter
can be measured and they must satisfy the conservation of energy
principle. Please state a steady-state conclusion that is incorrect.

> Second, my transient analysis does arrive at the correct steady state
> conditions. Third, (IMHO) it has value because it correctly describes the
> behavior of wave reflections at the match point. Note that I can not claim
> my transient analysis as original. It is clearly described in several texts ...

Exactly, I studied them in EE in the 50s. Nothing I have said disagrees
with those concepts.

> I will agree with you that your description of the steady state condition is
> correct as it relates to the forward and rearward traveling power in each
> line. Where I disagree is in your description relating these forward and
> rearward traveling powers to the wave reflections at the match point.

Again, every parameter can be measured and must satisfy the conservation
of energy principle. What is there to disagree with?

> Given that you understand wave cancellation I
> don't understand why you insist that a total re-reflection of power is
> required to describe the impedance match? These are contradictory
> positions.

Nope, they're not, Steve. The end result is identical in each case.
Nothing in the steady-state solution contradicts anything in the
transient solution. The steady-state solution is simply easier to

understand. The magnitude of the reflected energy certainly does
a turnaround and joins the forward energy.

> If a total power re-reflection occurs, no power is available for
> wave cancellation.

No power is consumed in wave cancellation so none is required for
wave cancellation. After the cancellation, we have power coming into
the Z0-match from the generator and there are no reflections on the
coax. We know we have reflected power (energy) coming towards the
Z0-match from the load. We know that reflected power doesn't make
it through the Z0-match and doesn't warm up the Z0-match. We know
that reflected power changes directions and joins the forward wave.
It is certainly not much of a conceptual stretch to say it was "re-
reflected" from the Z0-match.

We have generated waves, reflected waves, and forward waves that all
add up consistently to actual steady-state conditions. Adding in the
additional reflection phasors that cancel out completely before they
can actually come into existence long enough to be measured seems to
be an academic exercise of no practical value. Can you give an example
of why the average ham should be able to calculate the magnitude and
phase of the phasors that cancel out?

> Assume that the 300 ohm line is infinitely long so that no reflections from
> the 51.5 ohm load ever make it back to the match point. What is the source
> power delivered to the 300 ohm line? It is 50 watts, not 100 watts.

Of course, the same thing could be accomplished with a 300 ohm load. In
fact, using my previous example and switching the load from 300 ohms to
50 ohms will show exactly how the reflections build up so the transmitter
sees a virtual 51.5 ohms looking into the Z0-match. If the impedance seen
by the transmitter changes during transient buildup to steady-state, why
is it so difficult to conceive of the impedance seen by the reflections
changing during the same period?

> Now make the line 1/2 WL. The only thing that has changed is that
> reflections arrive back at the match point from the load. Re-reflections
> occur at the match point and in the transition to the steady state, the
> total forward power changes from 50 watts to 200 watts.

But after the transient response time is over, the transmitter sees 51.5 ohms
and thus delivers all of its power (energy) into the 300 ohm line. At that
point, the transmitter cannot tell the 300 ohm line from a 51.5 ohm resistor.
The reflections that would have occured to decrease the forward power in the
coax have been cancelled by complimentary reflections from the load. No power
is consumed in the cancellation because the Z0-match doesn't get hot. There are
no reflections on the coax so the reflected energy cannot go that way. The
reflected energy has no choice but to change directions and join the forward
wave.

Notice that we have no argument over fundamentals. We are disagreeing on
making something as simple as necessary, but no simpler. Funny how dropping

the words "virtual short" to describe the reflected energy turnaround, has allowed us to agree on the fundamentals.

You realize, of course, if one doesn't see a virtual 51.5 ohms looking into a Z0-match, then transmission lines are incapable of transforming impedances, those SWR circles on a Smith Chart are meaningless, and stubs don't work. :-)

Thanks for that info, Tom; that is the first I had heard about that. I will talk to Frank forthwith. If the published data in that review are not good, I want to see a Feedback. If the error is higher than would be expected, as a minimum, I want to see some public disclosure of the measurement uncertainty.

> supply system.

I can't speak with any authority on this one, Tom; the testing happened before my time here in the Lab. (I started in 1986.) I do note that the Review states:

"We experienced some problems with our AL-1200. According to the manufacturer, these problems existed with only a few of the earlier serial numbers.(ours is no.33), and they have been taken care of on later units. The first problem, low high voltage, was causd by an improperly wound plate transformer. The second, low power output, was caused by a defective tube. Tom Rauch, W8JI, of Ameritron was exceptionally responsive in helping us track down the problems. He promptly replaced both defective parts and the AL-1200 worked as specified."

I will add that we still have that AL-1200 serial # 033 in the ARRL Lab; if I get a chance, I will retest it, ensuring that it goes onto the Lab's stiffly regulated power supply. I think it would be interesting to take a look. BTW, the fact that this has been in the Lab, subject to all sorts of use and a bit of misuse by inexperienced ops, for almost 15 years speaks well for its design.

> Also the IMD measurements on an AL-800H first came out many dB better

> Let's face it Ed, you guys are like anyone else. Your measurements are
> never perfect.

I agree wholeheartedly, Tom, we are NOT perfect. Fortunately, at least under my oversight, and with the full approval, no, mandate, from the editorial side of the team, the ARRL Lab works closely with manufacturers to resolve such differences. I remember the IMD tests well, and your input helped prevent the need for a Feedback. I discovered that an error was being made in the way the tests were being performed and we were able to correct the error. The ARRL Lab IMD test fixture is now good to about -65 dB PEP on 3rd order and better than -70 dB PEP on the higher order. To my knowledge, only the correct IMD data from our series of exchanges was published.

> The problem isn't with making an error, we all do that. The problem is in never correcting the error.

I cannot speak for the time before I was involved in Product Review, but if I know that the Lab makes an error, I want to correct that error. Our internal processes are all designed to trap such errors before they happen, internally and, even more importantly, by working closely with manufacturers to resolve any questions about the test results. Had the ARRL Lab not been willing to do that, QST *would* have published a few of the test errors made in the Lab. My thanks go to the manufacturers, yourself included, who helped spot potential problems. OTOH, in most of the cases, the Lab's test data has withstood the manufacturer test, and was resolved as such to the satisfaction of the manufacturers involved.

The one area where I don't think we have satisfactory resolution, especially in light of what you mentioned in your first paragraph, is in the testing of the tuners. I would hope that my candor in raising the issue wrt the tuner testing in the first place helps demonstrate that I take the publishing of correct information seriously.

WRT the tuner testing, I want to know what the measurement uncertainty in that original set of measurements was and I want to share the results. If you are interested, I will extend an invite to you, Tom, to come to Newington and work with Mike Tracy, our test engineer, if you like. If you can get yourself here, I will pick up a night's stay in the local Holiday Inn and treat you to dinner.

73,
Ed Hare, W1RFI

Hi Robbie,

You will find ny tutorial with dimensions in wavelengths for the quadrifilar helix, for which I did the R&D research at in the 1970's. My R&D led to the development of all the antennas flying on NOAA's TIROS polar-orbiting weather satellites. My web page is www.iag.net/~w2du. There are two PDF files, one is a copy of my R&D report. Both appear in the new 2nd edition of Reflections, soon to be released by Worldradio Magazine.

73,

Walt Maxwell, W2DU

I didn't forget to, Steve, it is just not necessary. All of the values are
perfectly consistent without taking the impedance discontinuity into account.
Things should not be made overly complicated.

If I told you that there are two one million volt waves on every transmission
line but they are out of phase and cancel each other, would you believe me?

> +71.8 v in the 51.5 ohm line (100 watts) arrives at the 300 ohm line and
> sees an impedance discontinuity.

That's one way to look at it. An equally valid way to look at it is that
it sees a virtual 51.5 ohms and there are no reflections. This is the way
we have looked at it for 70 years or so. This is the way a Smith Chart
looks at it. This is the way stubs work. "If it ain't broke, don't fix it."
The older model works just fine. Good luck in trying to get wide acceptance
for something that doesn't work any better, is a lot more complicated,
and is impossible to understand by the majority of hams.

> Continuing, ...

I know this works, Steve, but so what? The earlier way of doing
things works just as well, is easier to understand, and lends itself
to fewer mistakes in calculation. I understand what you are saying
but I'm not going to throw away my Smith Chart which is based on
virtual impedances.

> The issue is simply technical truth. The truth is that a total
> re-reflection of power does not occur at the match point. Why not just
> explain it correctly instead of using a model that does not represent the
> physics of what is truly happening in the system?

The "truth" of religion is a God that cannot be detected. The "truth"
of your treatment is waves that cannot be detected. What's the difference?

100% of the magnitude of the measured reflected energy changes directions
at the Z0-match point. Since that gives the correct answer, why complicate
things with undetectable, unprovable "technical truth"? I submit that you
don't know the technical truth and quantum physics will someday revolutionize transmission
line
theory.

The technical truth is that the sun doesn't rise. Yet, every day on the TV
weather report we see the weathercasters giving the sunrise time.

> Again, you are only measuring the steady state *totals*, not the individual
> components.

I have to side with Aristotle on this one. "A is A". A thing is what it is.
If it cannot be proven to exist, then for scientific purposes, it doesn't exist.
If the components cannot be broken out and measured, the only place they
continue to have an independent existence is in your mind. It's like mixing
a glass of water from California and a glass of water from Texas and
claiming that California molecules and Texas molecules still exist.

> Perpetual motion??? How about circuit theory. 122.474 volts (50 watts in a
> 300 ohm line) adds to another 122.474 volts (50 watts in a 300 ohm line)
> resulting in a total voltage of 244.94 volts (200 watts in a 300 ohm line).
> In any impedance, if the voltage doubles, the power goes up by a factor of
> 4. This is not perpetual motion, it is simple circuit theory.

So if I phase lock my IC-706s and drive the same 50 ohm load with both of
them outputting 100 watts, I can deliver 400 watts to the load. If so, I
can use 200 watts of the 400 watts to power the IC-706s. That's perpetual
motion, Steve.

> When the 100 watts of reflected power
> arrives at the match point, it transmitted 50 watts of power back into the
> 51.5 ohm line. These two powers are 180 degrees out of phase.

If there were any reflections, we would be able to measure them on an SWR
meter which is capable of seperating out two powers that are out of phase.
Please put your SWR meter on your coax and prove the existence of out of
phase powers. My SWR meter indicates only a single phase of power on the
coax. That reflected power needle doesn't move at all.

>If you can offer anything specific that you believe to have been an error, please let me know.<

Tom has mentioned some specific examples involving the Lab. Another problem appears to occur because of inadequate communication between the staff reviewer and the Lab staff in preparation of the Review.

Specifically, the IF filter in the MFJ-9406 was criticized for having marginal selectivity because splatter could be heard from nearby stations during a contest (obviously, the reviewer was unfamiliar with how "dirty" signals get in VHF contesting). So the filter was criticized, but it's actual selectivity and shape factor were never tested by the lab to verify the claim.

In the MFJ 40-meter Cub review, the rejection of out-of-band SWBCI signals was criticized by the reviewer. During the subsequent lab eval, it was found that the wrong caps were supplied and 68 rather than 6.8pF coupling caps were used in the passband filters (the receiver and transmitter filters use the same value coupling cap). No wonder out-of-band signals were heard! But, there's no good mechanism for correcting situations like this.

Of all the League reviews of my designs, I've enjoyed good rapport with the Lab commend their willingness to take a second look and to solve problems if there are any. And, sometimes I'm sure I've gotten the benefit of the doubt! But, I still think there should be an erata box in the Review section for when something goes wrong or when the Lab finds something blatently counter to the reviewer's observation.

> wave.
>

Cecil:

You are correct that the ZO match does not get hot. You are also correct that there is no rearward energy flow in the 51.5 ohm line. We agree on this.

Rearward energy flow on the 51.5 ohm line ceases because of wave cancellation not because the *total* reflected energy (in the 300 ohm line) has no choice but to change direction. A *total* re-reflection of this energy does not occur, ever. This statement contradicts basic transmission line theory. Look at any of the texts you have (ex. Walt's), I would appreciate a reference to someone actually stating this.

The rearward flow of energy in the 51.5 ohm line ceases because of a wave cancellation process that continues throughout the steady state. It is always occurring. It is a continuous process. At all times in the steady state, there is 50 watts reflected at the match point and 50 watts delivered back into the 51.5 ohm line from the 300 ohm line. The *net* rearward power flow at the match point is 0 watts.

The law of conservation of energy. I'm not sure why you think there is a problem with this in my discussion.

Conservation of energy at the match point:

Transmitter delivers 100 watts to the match point. 50 watts reflected, 50 watts delivered to 300 ohm line.

100 watts of reflected power arriving at the match point. 50 watts re-reflected, 50 delivered to 51.5 ohm line.

The 50 watts delivered into the 300 ohm line adds to the 50 watts re-reflected at the match point and the *total* forward power is 200 watts. Vtotal = V1 + V2. Power = |Vtotal|^2. As I said, 100 watts forward + 100 watts forward cannot equal 200 watts forward. This is all simple circuit theory, demonstrating why the 100 watts is *not* totally re-reflected.

Cecil, we are again starting to go around in circles.

Really? Whether a generator is generating 100w or 85w depends upon
the location of the circulator? What if the circulator is halfway
inside the generator box? Does the generator then generate 92.5
watts? :-)

The Smith Chart works great, it is pure genius. It is a graphical tool used to perform *steady state* design with *steady state* impedances.

>

I know you must be enjoying this more than I.

Lets connect the two IC-706's to the same 50 ohm load (not recommended for those without very good isolation circuits). So, I hope that each has some very good internal protection to take the power delivered to it by the other. When you connect two to the same load, the load impedance seen by each would be the 50 ohm load in parallel with the output impedance of the other transformed to the 50 ohm load. Let's forget about all that and assume that each sees a 50 ohm load and each "delivers" 100 watts to this load.

In this case Cecil, you would be driving the 50 ohm load with two equal voltages in parallel. 100 watts into 50 ohms translates to a voltage of 70.71 volts. The total voltage at the load resulting from connecting the two in parallel would still be 70.71 volts and the total power delivered to the load would still be 100 watts. No perpetual motion machine, still simple circuit theory. Does help the current drain on the IC-706's though (unless you fry them of course)

> --

I was unaware that the SWR meter could independently detect two steady state powers traveling in the same direction simultaneously and then present a relative measure of both via the meter reading. I thought that the SWR meter presented a relative measure of two steady state power levels traveling in the opposite direction - like a ratio of reflected power to forward power. In the steady state, all we can measure is the *total* power in each direction.

Try this again with a TDR.

As this discussion starts to deviate from the subject, I will respectfully bow out.

I think that you are right. I have had 3 Fords and they all had problems with noise. 92 Bronco with the 5.0 V8, 98 Exploder with the V6 and now a 98 F150 with the V6. Put the fuel pump kit in the Bronco and that was a waste of time. The other 2 vehicles had ignition noise. Maybe I will learn one of these days. Go with a Ford and get the noise or go with a chevy and get mechanical problems(that should get a rise)

Ok Chuck, I'll bite.

It's not mechanical problems with GM vehicles, it's all those damned squeaks and rattles that drive a guy crazy. I have owned a handful of GM vehicles and all of them were well over 150K miles before needing any serious repair. My current driver is a '93 Ford Explorer. Man, what an RFI nightmare. Ignition hasn't been the problem, it's that cheapo, wanna-be a real fuel pump that's the trouble. If I didn't like the vehicle so darned much, I'd trade it.
I like the new GM Jimmy/Blazer but when I sit in one sardines come to mind, not to mention the bump I got when I banged my head getting out of it. =)

Oh well, I sold the MKIIG and got a nice base rig. If I am going to take HF on the road, I'll just wait until I setup camp and then break out the laptop for a little PSK31...

For 40 and 10 tie the coax shield and center conductor together and it
becomes what is known as a "tee vertical". Sort of. It won't be resonant
on 40 & 10 but it will radiate. You'll have to use a wire tuner to get the
swr under control.

You don't say what bands. So I'll assume 20 though 10. A good beam will
eat a good vertical for lunch overall. It's that simple. But a good
vertical can still do a good job. And much cheaper and easier to put up.
But once you compare a beam with a vertical and see the difference in
F/B capability and gain you will be spoiled and probably dump the
vertical. It really is that much difference if you are using a good 3-4
el yagi or so. And remember it's reciprical. You receive much better
also. A barely readable signal on the vertical will be Q-5 on the beam.
Or 95% of the time anyway... MK

Classic analysis would say that when the forward power is 100w and
the reflected power is 15w, then the generator is generating 85w.
Do you think that's an absolute truth or do you think that the
generator may still be generating 100w and turning the 15w reflected
into heat? Or somewhere in between?

>I have installed a 20 meter diapole at my house. I only have room for
>this antenna and I was wondering how to get it resonant on 40m and 10
>meters.

There are a number of techniques you could try. One is to make a loaded, trap dipole. I don't recall any articles that show how to design a loading coil and a trap into the same antenna, though.

See:

http://www.arrl.org/tis/info/trapped.html

One other way that will work reasonably well is to feed the dipole with ladder line and use an antenna tuner to load it up on all bands. There is no need to have the dipole be resonant on 20 meters, so put up as much wire as you can and feed it in the center with ladder line. Longer is better and it is okay to bend the antenna around a bit, but try to keep the bends at angles > 90 degrees.

If you can go a bit longer than the ~33 feet your 20 meter antenna takes up, perhaps with some wire bending, the article at:

http://www.arrl.org/tis/info/pdf/9506059.pdf

might be of interest.

RRAA readers might enjoy the large number of antenna articles available for download from the ARRL TIS pages:

Because currents *cause* fields. If there is zero current, the fields
do not continue to exist. IMO, all these phantom currents and phantom
fields border on a religion that takes us away from reality.

> The partial reflection/partial transmission representation results in
> the expected impedance (as computed using E/I) on each section of line,

How about the components that were there yesterday? Are you going to
continue to visualize them? Are you going to carry the noise from the
Big Bang along in your model? Dropping the canceled signals from the
visualization simplifies the model. Maintaining an infinite number
of reflections complicates the model. The results are the same either
way. It seems like a no-brainer to me. Can you explain exactly why
"phantom reflections" is a superior concept to a "virtual short"?

>wall. Right! Just behind the rear of the t.v!

It is an antenna question because the biggest factor in all this is not the distance from the TV to the receiver, but from the TV, its antenna and electrical system and your receiver's antenna.

I know of two main sources of noise from TVs. The first is caused by harmonics of the TV's horizontal circuitry. This is characterized by a buzzy, somewhat broad (2-3 kHz) interference every 15.75 kHz. It can be radiated directly by the TV, but is often radiated by the antenna/cable connection or the AC line cord. First, try a high-pass filter on the TV's input lead. You can then try a common-mode choke on the TV antenna connection (use a Palomar F-240-43 core, about 10 turns of wire. Do not sub ferrite beads or one of those Radio Shack clamp-on ferrites). Next, I would try a common-mode choke and an AC line filter (Radio Shack catalog 15-1111) on the TV's ac line cord.

If at all possible, an even easier cure might be to locate your antenna farther away from the TV and its wiring. If you are using an end-fed wire for an antenna, consider putting a coax-fed antenna outdoors.

See http://www.arrl.org/tis/info/rfigen.html for more info. The ARRL RFI Book, http://www.arrl.org/catalog/6834 also has some good info.

Roy, your experimental results confirm what I have observed over the years with my IC-730 (vintage 1982) used in several mobile installations with a variety of antennas.

The rig seems remarkably tolerant of high-SWR loads up to a sensible level. I will be using a new IC-756 PRO on the next motorhome jaunt, instead of the 730, and it will be interesting to compare its tolerance level with the 730.

> to exist. In the other, the cause ceases to exist.

Why is there a big difference between fields canceling and currents canceling? For the balanced line, picture two plane waves, one from each wire, at some distant point. The E-fields are anti-parallel. Since the waves are going in the same direction, the Poynting vectors are parallel. That makes the H-fields also anti-parallel. The E-fields cancel, the H-fields cancel, and the line doesn't radiate. For the transformer, there are two sets of voltage waves and two sets of current waves on the line prior to the transformer. One voltage wave is due to partial reflection at the impedance junction and one is due to partial transmission. The same with the two current waves. Both sets are traveling back toward the transmitter. The voltage waves are 180 degrees out of phase and the current waves are 180 degrees out of phase. The voltage waves cancel, the current waves cancel, and the transmitter is happy. An exact analogy.

The partial reflection/partial transmission representation results in the expected impedance (as computed using E/I) on each section of line, and exactly the right amount of power delivered to the load. And all the wave components can be easily visualized, even by the new inexperienced ham.

"Ed Hare, W1RFI" wrote:

> As an aside to the data, what is the present state of your earth? Wet? Dry?
> Do you have an estimate of the characteristics of your soil?

Here's a gardener's answer: the soil here is about half way between dry
and damp. There is a lot of rock, left here (NY) by a glacier way back
when. I hit clay when I dig down about 12" - if I can get past the rock :-)

When I built the dipole out of #6 wire - the one that was attached to the
8' 2x4, I tried it over the lawn, and then tried it over the blacktop driveway
and couldn't detect a difference on the MFJ.

Yesterday, I assembled an MQ-2 (Mini quad from TQM). It
covers 6 bands (20 - 6). I measured the swr at 5' above ground, and it
matched almost exactly the swr charts provided by the manufacturer.
I put the results into a lotus 123 spreadsheet - I can send it to you
if it would be of any use. What bearing it has on our discussion is
not apparent to me, except that it at least shows that the MFJ seems
to be working as it should. But I worked Brazil on the MQ2 it - off the side -
on 20 today, right after I installed it on the roof. K2GUC (I think
that's close to his call) another poster on this NG who lives about
5 miles from me, may have heard me do it - I heard him. But I digress.

If I can figure out how to accurately measure R vs Z, I'll try to do a
number of measurements of a dipole at various heights above ground.
That, and the other experiments I mentioned earlier, aren't going to
happen soon, but I'll post them when they do. A friend - WB2UAQ -
has seen a pretty wide swing in the impedance of his horizontal loop
(about 260 feet, roughly square) with change in height. I can ask him
if he has a record of the values he got when messing with it.

Ok I have another question. Since you guys were very helpful in helping me with my Helical antenna question, maybe you can help me with this one.

I have some CATV hardline. I remember a few years back articles and people selling transformers and the like. I was wondering if any one had any thoughts good, bad etc on the use of 75 ohm hardline.

Would this hardline be suitable for a set freq. or can I get away with using it on HF
etc.

.

Thanks and 73
Matt

Sorry David. I misunderstood your original problem.
You might check with a marine supply company and see if they have the bronze bolts you need in stock. They are used sometimes to connect rudders to the rudder posts of boats. I don't know where you live however in Seattle there are plenty of such outlets for this type of hardware.

Also your concern about dissimilar metals is a good one. Galvanic joints can cause rectification and TVI. Stainless against copper or bronze may result in a galvanic joint in the presence of moisture.

Good luck

Dick K7RNZ

>Radio Antennas, introduced by Senator James Brulte (R-Cucamonga). Oh,
well,
>let's try it again come next session.

Here's the Governor's statement:

To Members of the California State Senate:

I am returning Senate Bill 1714 without my signature.

This bill would require the Office of Planning and Research to: (1) prepare and publish a technical assistance bulletin for use by local planners in the preparation of local ordinances regulating amateur radio antennas; (2) prepare a model ordinance suitable for local regulation of those antennas; (3) and report by July 1, 2001, regarding any recommendations for changes to the state statutes regarding regulation of amateur radio antennas.

This bill may encourage local officials to accommodate the needs of amateur radio operators when adopting ordinances. The cost of this bill however, is not included in the Budget Act of 2000. Additionally, this is a local rather than a state issue.

Sincerely,
GRAY DAVIS

Some one mentioned the Cross Field Antenna in the context
of the fractal discussion. I found a couple of
interesting items in that regard.

http://www.antennex.com/general/_general/00000021.htm

"My issue is not one of whether the so-called 'CFA'
works, or even how well, but that the theory with which
it is credited is unfounded and quite ridiculous - as
anyone genuinely knowledgable in EM theory will tell you.
There is nothing remarkable about the anatomy of this
device - it can be modelled using finite element methods
as can any other conducting structure purporting to be
an antenna. A finite element model would soon reveal the
true comparative performance of this structure versus
other more established designs. I'm not sure if anyone
has actually done this since those acquainted with these
methods would immediately see the folly of the 'CFA' and
give it a wide berth..."

Could "fractal" be substituted for "CFA" in the above?

Here is an amusing link, where the phrase "April Fool's
joke" is applied to the CFA. (A common theme with
unappreciated inventors?)

Microwave and Optical Technology Letters

Volume 25, Issue 6 2000
Pages 429-435
Chang, Jungmin; Lee, Sangseol
Hanyang Univ, Seoul, South Korea

Abstract

A new fractal geometry of the cross antenna, which belongs to the traveling-wave antenna class and follows the contour of a cross, is presented. In the conventional type of traveling-wave antenna, the total length of the radiating conductor increases as the order of fractal expansion increases, but this increase of the length of the current path degrades the performance of the antenna. To reduce the antenna performance degradation, a hybrid fractal antenna is presented, which divides the entire fractal structure into some smaller ones, and connects each smaller fractal group with a power divider circuit. The secondarily, thirdly, and fourthly expanded hybrid fractal cross antennas are fabricated, and their performances are examined by measurements. The influences of the fractal order on the antenna performance are examined. [Author abstract; 10 Refs; In English]

Microstrip fractal patch antenna for multi-band
communication

Hara Prasad, R.V.; Purushottam, Y.; Misra, V.C.; Ashok,N.

Defense Electronics Research Lab, Hyderabad, India

Abstract

A novel square microstrip fractal patch antenna in a
Sierpinski carpet is proposed for three-band operation.
Measured results indicate that the return loss is better
than 10 dB and that the gain is greater than 7 dB in
each band. This antenna is an attractive candidate for
wireless, satellite and mobile communication
applications. [Author abstract; 6 Refs; In English]

Hi OM,

You are probably under a false assumption as to "what" is patented (read the claims - the only content that counts). After all, this patent you speak of is NOT a design patent (that would protect a particular form), but is rather a method patent (that protects how something is done).

There is no one here practicing that art by any stretch of the imagination. I can't imagine why anyone would, either - especially at HF.

You will note that once the patent issued, the claims of "possible" infringement dropped to ZERO and the bogus notion of copyright moved into its place in this wobbly logic. That was why it was so amusing that I "might" be subject to legal action (as we all "might" be if we live long enough - duh, sure and as Ed McMahon would say "you may already be a winner!").

For other amusing insight, compare the statements made before and after publication by the Patent Office. It certainly appears the patentee hadn't a clue as to what was in the patent, what was protected, or what the coverage was. You may see pictures of several familiar fractal forms, but NONE of them has been patented by Fragile Antennas in this last round - only a method to tune them. I will stick with EZNEC to perform this loathsome chore. The publication was a tremendously boring non-event.

>out of two 100w waves.

I can do that. If I set the 706's at 100 watts on different
frequencies and combine them, the PEP power will be 400 watts. The
average or effective power would be 200 watts, and the individual
radio power 100 watts.

I sure hope that isn't what we are doing!

What exactly are you talking about? Could you be more technically specific
than "If I can't measure them they don't exist". The steady state is the
net result of all wave transients in the transmission line system. The
transient signals are not undetectable, nor are they unmeasureable. Your
power meter is just not the right equipment.

I have never spoken of phantom waves. Do you understand the concept of wave
cancellation in a transmission line? Rearward transient waves combine to
cancel at the match point such that there is no net rearward flow of power.
Why is this unbelievable simply because your steady state power meter can't
measure this? A steady state power meter will only measure the sum of the
transients.

Cecil, try this. Drive a matched load with 100 watts of forward power in
the transmission line. Measure the voltage at the matched load. Now
increase the power output on the transmitter until the voltage across the

matched load doubles. Measure the forward power in the transmission line.
Is it 200 watts or 400 watts?

>
> > There is no doubly-phantom power in my description.

> two terms of phantom power. (I left out phase to simplify.)
>

You seem to be developing a habit of misquoting me.

In the steady state, the net rearward voltage is equal to 0 volts at the match point. The net rearward current is equal to 0 amps at the match point. Therefore, the net rearward power flow is 0 watts.

In the forward direction, total power is *not* equal to V1*I1 + V2*I2. I *never* said this, you did. I.e, you claim 100 watts + 100 watts = 200 watts. The summation of power is found from Vtotal * Itotal (phase = 0). Votal = V1 + V2. In our example, the value of V1 is the driving source voltage (which does not change) and the value of V2 is the summation of the transient re-reflections occurring at the match point.

I think this will be my last response.

Thanks Cecil.

Regards,
Steve

> only one who can tell me what he means.

Since you two seem to be having communications problems, maybe I can tell you better than he. All kidding aside - he says the 100w of *generated* power would cause 173 volts in the 300 ohm line if it simply flowed unmolested through the Z0-match - as if it had encountered a 6:1 transformer. I don't know why he thinks it should act as if it had encountered a 6:1 transformer because no such transformer exists.

But he takes that non-existant 173 volts, adds it to the existing 173 volts from the reflections, and gets 346v, a result that is too high since the actual forward voltage in the 300 ohm twinlead is 244v.

Truth is, the generated voltage does not magically jump from 71v to 173v as if a 6:1 transformer existed. And 71v + 173v actually does equal the 244v forward voltage on the 300 ohm twinlead. The generated energy waves continue to see approximately 50 ohms for some short distance into the 300 ohm line. They do not see a 6:1 transformer.

The fract is that Clintonistas "streamlined" the patent laws to the point that one can get patent for any garbage (just read the incoherent freaky patent) and then it is up to the patentee to defend it in the court. (Thank you lawyers for your election fund contributions!) Just like Clinton vetoed the law on limiting frivolous law suit "rewards".
The dismantling of America continues. Give your hard drives to Chinese, you will "find" them behind the copier.
Standby for more crap.

VE9SRB wrote:
> The transient signals are not undetectable, nor are they unmeasureable.

Some become undetectable and unmeasureable after steady-state has been reached and IMO have therefore ceased to exist. The steady-state reflected power(s) that you propose on the coax of a Z0-matched system exist only during the transient buildup to steady-state. After steady-state has been reached destructive interference eliminates all reflections on the coax. You say they are still there even though they are undetectable and un-measureable. Thus the phantom signals label. My Mother says there are unmeasurable and undetectable angels watching me all the time.

> I have never spoken of phantom waves.

I don't blame you. If I had invented the concept, I wouldn't call them by their correct name either.

> Do you understand the concept of wave

During steady-state, **NOTHING KNOWN TO MAN** can measure or detect them so you cannot even prove that they exist. Do you understand that there is zero power when the voltages and currents all cancel to zero?

Voltages, currents, and powers don't squirt out of the Z0-match and then cancel. They cancel at the impedance bump point and nothing squirts out of the Z0-match back toward the transmitter.

> Cecil, try this. Drive a matched load with 100 watts of forward power in
> the transmission line. Measure the voltage at the matched load. Now
> increase the power output on the transmitter until the voltage across the
> matched load doubles. Measure the forward power in the transmission line.
> Is it 200 watts or 400 watts?

Nobody is arguing anything remotely resembling the above so it must be a straw man. Your basic problem is thinking there exists a virtual 6:1 voltage transformer at the Z0-match and it does NOT exist. The 71v generated voltage in the 50 ohm coax is not magically transformed into 173v in the 300 ohm line. It remains 71v as it flows unmolested through the virtual 50 ohms at the Z0-match. The impedance seen by the generated waves changes slowly away from 50 ohms as predicted by the Smith Chart. The virtual impedance has completely overshadowed the Z0. In fact, on a line with reflections, one can guarantee that Z0 will NEVER be encountered by an incident wave

with a different characteristic impedance.

> I.e, you claim 100 watts + 100 watts = 200 watts.

Earth to Steve - Earth to Steve - Power is a scalar.
100w + 100w *IS* equal to 200w

Hi Steve,

Please don't be distracted.

I'd like to know how you arrive at the conclusions you reached
regarding voltage doubling in the transmission like and power
increasing by four.

I assume you mean actual power, and not VAR power. If you do mean VAR
power, then I can't follow how we can ignore the phase angle when
talking about actual power.

I can't follow why the voltage doubles, without talking about a
specific point in the system.

I'm really trying to understand this and need a practical example.

That was my conclusion also. The patent essentially said if you place one fractal thing in front of another and rotate it or alter the length of wires, it might be used to "tune" the system in a few non-amazing ways.

I couldn't find any other claim.

I suspect if someone wanted to tune an antenna that way, the whole patent could easily be tossed out. Mutual coupling effects are well known, and have been for years.

IMO, it is another one of these nuisance patents designed to be a fake feather in the cap of the holder or a slight thorn in the side of someone who wants to use what is an obvious system of tuning.

It was a method of tuning that was patented, nothing more. Unless I missed something in all the technobabble. Has anyone else found anything other than this one single claim?

> You state that, but the reason isn't clear to me yet why you say that.
>

I state this for a very simple reason. The transmitter is energized, it sees the ZO of the 51.5 ohm line and delivers a forward traveling voltage to that line equal to 71.764 volts. This is a forward traveling power in the 51.5 ohm line equal to 100 watts.

This forward voltage arrives at the junction between the 51.5 ohm line and the 300 ohm line. It sees the 300 ohm impedance as a discontinuity. A reflection is created at this impedance junction. The reflection coefficient is equal to +0.707. The voltage reflected at the junction is +50.737 volts. This is a reflected power in the 51.5 ohm line of equal to 49.985 watts. The total voltage transmitted into the 300 ohm line is the total voltage developed at the impedance discontinuity. This total voltage is equal to 122.501 volts (71.764 + 50.737). This is the forward driving source voltage in the 300 ohm line. The forward driving source power in the 300 ohm line is therefore 50.02 watts.

The rest has been explained in several of my previous posts.

>

> 400 watts PEP out of the discussion.)

>

I did not say that you could convert 100 watts of source power into 400 watts of actual power. Cecil misquoted me and misinterpreted my statements and asked how he could hook up two 100 watt transmitters and get 400 watt of power. I did not once claim that you could do this.

> >Another way to think of this is connecting batteries in series across a

> >power dissipation be 24 watts? No, it is 48 watts.
>
> Only when the currents also double, and now the power from each
> battery is 200 watts. You have changed the source power.
>

In this case the current does double in the load, since the voltage in the load doubled. When this occurs, the V*I product goes up by a factor of 4. In this case, the power from each battery would be 24 watts. We cannot violate the principles of conservation of energy. If we deliver 48 watts to the load, the source can only be delivering 48 watts. In each battery, the effective V*I product is 12 V * 2 A = 24 watts.

>
> You claimed, if I'm not mistaken, a single 100 watt transmitter could
> produce 400 watts of power at multiple points in the system...none of
> which were described to be VAR power measurements.
>

I did not claim this at all.

Cecil claimed that in his example, that the forward source power to the 300 ohm line was 100 watts. He then claimed that the re-reflected power in the 300 ohm line was 100 watts. He said that they then added together to be 200 watts. I said, that *if* the source power were 100 watts and *if* the re-reflected power were 100 watts, the forward power would actually be 400 watts.

The point being that the actual forward source power in the 300 ohm line is 50 watts and the actual re-reflected power in the 300 ohm line is 50 watts. 50 watts forward + 50 watts forward equals 200 watts. Back to adding voltages. In this case, the transmitter is delivering 100 watts of power to the match point, 50 watts into the 300 ohm line and 50 watts reflected. The reflected power into the match point is 100 watts, 50 watt re-reflected and 50 watts delivered back into the 51.5 ohm line.

Cecil took my comments and applied them incorrectly to another example.

> Let me ask my original question again:
>
> Can you give me an example of how, by changing only the line match, I
> can cause the voltages to double and current to double at any single
> point in the line while they remain in-phase (so power is multiplied

> by four) WITHOUT doubling the power of the generator?
>
> I want to build a system to prove you are correct. Can you help me
> build one?
>

I did not say that you could do this in this manner. What I did say was that when the driving forward source voltages adds to a re-reflected forward voltage having the same value, the total forward voltage increases by a factor of 2 and the total forward current increases by a factor of 2 and the total forward power increases by a factor of 4. The source power does not change in this case at all.

It's obvious you haven't bothered to read the analogy I posted several days ago.

> Please give a reference [snip]

I'm glad you're looking for references. Here's one: A description for the quarter-wave transformer is presented in Electromagnetics by Kraus and Carver, p 509 to 520 in the second edition. This description is based on *standard* transmission line theory and your so-called "phantom waves" are an integral part of it.

Here's a quote from another reference: From the first paragraph of Section 5 of Slater, "Thus we see that at a discontinuous boundary between two lines a reflection will be set up... If a wave approaches such a boundary from the left, there will be reflected wave in the line to the left, a transmitted wave in the line to the right. Similarly, a wave approaching a boundary from the right will give rise to a reflected wave on the right, a transmitted wave on the left. [Here's the good part]-> By assuming both a reflected and a transmitted wave in each section of line and imposing the boundary condition ... we have enough equations to determine all the amplitudes of the waves and to solve the problem completely." Notice that Slater sez "each section of line", not "some sections". He doesn't add "(except for inputs to a transformer)." This quote is directly applicable to the partial reflection/transmission model of the transformer.

The Kraus model has been around at least since 1973. The Slater quote is from a Dover reissue of the original first published in 1942. So for at least 58 years, partial reflection and partial transmission have been fully accepted concepts. I believe people on this NG are savvy enough to follow and fully comprehend this concept.

I want to thank you again for giving me the opportunity to get the word out to a LOT of people.

We who were on the "SB-1714" Task Force were amazed that the
Governor vetoed the Bull because both the State Senate and the
Assembly passed the Bill UNANIMOUSLY.

In typical California style the legislators decided to make a
"study project" out of what all the other states with similar
legistation did as a "done deal", and the veto was solely on
the basis of "no funds allocated".

The issue was the "costs" involved ... heck, I could sit down
and crank out the "Technical Assistance Bulletin" and Model
Ordinance over a weekend at no cost to the taxpayers - I did
both for a client county two years ago and it's still on my
wordprocessor.

We'll try next year.

Really??? - 71 volts in a 300 ohm line is 16.8 watts of power, not 100
watts of power. If your 100 watts of forward source power were correct, the
71 volts would have to be transformed into 173 v.

The impedance discontinuity at the junction is a function of the reflection
coefficient at the junction. The reflection coefficient is +.707. The 71 v
is transformed into 122 volts in the 300 ohm line - 50 watts of power.

An impedance discontinuity always exists at the junction between the two
transmission lines. The steady state match is a result of rearward voltage
cancellation that only occurs because the impedance discontinuity always
exists.

>
> > 100w + 100w *IS* equal to 200w
> --

Really??? Like 71 v in a 300 ohm line is equal to 100 watts of power. Take
the voltage associated with 100 watts of power in a 300 ohm line. Double it
and calculate the total forward power.

The problem is that we cannot think of light or radio waves as *just* waves or *just* objects (like tiny little bb's). If two waves cancel, as in my example, then photons cancel also, not by some kind of violent explosion or annihilation, but because the waves are out of phase.

This is a difficult idea, but it really is important to wear two different hats when we talk about electromagnetic wave and photons. They must both obey the same rules. The tough part is this: they are not in reality *different* entities, but two different ways of expressing the same set of rules.

I am sure this is right.

Hi Tom!

I believe the phrase is 'patent pending'. Do you understand what that means? Or you under the impression that a new technology may only be awarded one patent?

Actually, it's PATENTS and patents pending.

Hope that helps. If not, please consult a patent attorney as I find many incorrect statements in your comments, even here.

>
>73 Tom

Hi Tom,

All claims appear to be bloated and ambiguous except to a lawyer
(something about an ugly child only a mother could love). I speak
from the experience of having some 300+ claims allowed among my 5
patents and having had to read more than one action to dismiss, and
then writing appeals. The key factor to this fractal patent list of

claims is found in the first one, which through the successive claims is constrained and reduced in scope for this patent (not remarkably written either). In effect, there is only one claim with subordinating clauses for a process to tune an antenna. Not much to speak of. I would suggest my own patents for pointers, but I hesitate to impose that soporific on anyone.

If you read the text and read the claims you will notice a disconnect between the two. Simple fact of the matter is that the original claims (suggested by the textual content) have NOT survived and the review process whittled down the application to the method now patented. This is, no doubt, a source of great disappointment for the patentee. My original patents probably totaled 1000 claims (easy to lose track when the Patent Office sends you a final notice of rejection four or five times for each application - ah! the process of appeal, what a game). The difference is that my text and illustrations probably exhibit more coherence with the surviving claims than most patents (it takes the master's hand to accomplish this).

In general, the text and the images are of no particular merit, except where the images are referenced specifically in the claims. Many naive readers would assume that upon seeing those familiar fractal designs, that those same images and their application as antennas were covered by the patent publication. NOPE, NADA, NOT IN YOUR LIFETIME.

This would not be possible as those topics were revealed here in this forum more than 2 years before the patent was applied for. Many of these images where published at my various web sites more than 4 years ago. This created prior art which now disallows the patentability for anyone. I would suggest that being demanded to provide notice that the design elements were "patent pending" are now exposed to have been a fraudulent statement (base stupidity works as a defense - maybe). But to be fair, I am sure that upon examination of the exact statements made, these were inferences (as much of that correspondence is), with the ambiguity leveraged to present the illusion of legal authority.

Another point, you can LOSE your patent if you are aware of infringement and fail to act (and act means more than posting a "notice" :-> to a newsgroup).

And yes, I have consulted a patent attorney, my partner. He smiles and informally extends his regrets to the aggrieved party. He is one sharp dude who averages 4 times the claims as the patent we are currently considering. He is the one with the master's touch. Claims are the asset - nothing else.

>51.5 ohm line equal to 100 watts.

OK, we can round numbers if you like. I like to only use my fingers
and toes whenever possible. We have about 70v RMS and 1.4 amperes.

The problem is, we don't have that as a transient on a conventional
transmitter unless it has a problem like a slow TR relay.

What we have is a slowly changing voltage that gradually builds over
many RF cycles from zero to about 70 volts (in a perfect transmitter).

If the transmitter has a bandwidth many times the operating frequency,
we can have a situation where the output appears close to full voltage
instantly. Like a TDR would generate.

I assume this discussion centers around a system with an extermely
wide bandwidth transmission, much wider than conventional TV
transmitters. Amateur radios and even TV BC transmitters certainly
can't deliver such a signal.

But let's get past this, and assume a transmitter does behave that
way. I'll assume we have a transmitter up and running, and then at
some point after the tank circuit and harmonic filtering we have a
bounceless switch we open and close. That would allow me to create
the outgoing wave you describe.

I assume also we are working with lines that have very long delay
times compared to the rise time of the transcient.

Because that isn't something I do not consider in my normal line of
work, I'll have to ask questions as we go along. But then that's how I
learn things, and that's what I really enjoy and appreciate about this
newsgroup.

>This forward voltage arrives at the junction between the 51.5 ohm line and
>the 300 ohm line. It sees the 300 ohm impedance as a discontinuity. A
>reflection is created at this impedance junction. The reflection
>coefficient is equal to +0.707.

I assume the angle of the reflection is zero degrees so you are able
to just ignore it? ...and the reason phase angle is zero is because
the 300 ohm line is infinitely long for the high-speed transient pulse
we are considering...which is nothing like anything from a real
transmitter we would use?

Now here's what I don't quite remember. Does the reflected voltage add
to the incident voltage at that point? What about the current?

As I recall, when the load impedance is higher than the sourcing
impedance at a mismatched junction the voltage reflection is more
in-phase while the current caused by the reflection is to some extent
out-of-phase with the arriving wave. The end result is the voltage
increases while the current decreases.

That's why an open lossless transmission lossless line steps up
voltage to infinity, while a shorted lossless line has zero voltage
and infinite current...if we could somehow feed power into a line with
voltage and current 90 degrees out-of-phase.

I'm lost at this point. How do we double the voltage without reducing
the current?

>The rest has been explained in several of my previous posts.

I haven't had time to follow all the posts until now, and I know your
not going to be like someone else would be and tell me to go back and
read them all! I need to understand the stuff above before going on!

>> I understand the VAR power can be any value, but I haven't noticed use

>the match point, 50 watts into the 300 ohm line and 50 watts reflected. The
>reflected power into the match point is 100 watts, 50 watt re-reflected and
>50 watts delivered back into the 51.5 ohm line.
>
>Cecil took my comments and applied them incorrectly to another example.

OK.

It's beginning to make some sense to me now. It seems like the results
would agree with the more simple method of considering the reflected
wave in a steady-state condition....which for virtually all of us is
good enough.

So what is the argument about? With a typical HF transmitter, envelope
rise time is limited to 200 uS or longer. That's 360 full RF cycles on
160 meters, the lowest amateur band in the USA. With CW transmissions,
it is longer yet.

Even if the transmitter has a severe bandwidth problem, rise time
would still take many dozens of RF cycles.

Few of us have five mile transmission lines in use with defective
transmitters that are hundreds of kHz wide, so what's wrong with using
the more simple reflected wave analysis method?

I'm just trying to get a handle on what the fuss is all about.

Now if I was running phase sensitive broadband transmissions up lines that were many many wavelengths long, I'd worry about transient responses.

Hi Bart--

Actually, Tom suggested pretty much the same thing by combining two 100 watt 706's operating on different frequencies.

Yes, that's why the voltages, currents and energy distribution is
different on the two sides of the boundary.

Well, Chas,

I can't agree with the mechanical troubles on Chevrolet, either. I went to Chevrolet for good after having several Fords that, not only gave me noise trouble (to the point that a radio was almost unusable), but left me stranded a number of times. I abandoned Ford for good in 1973 and never looked back. I've had 5 Chevrolets since that time (I used to trade just to keep up with the Joneses when I was younger)--two of which I own now. The '87 Celebrity station wagon I bought new in August '87. It now has 197,000 miles on it. It has never had the engine or transmission opened except for routine maintenance and they are both the originals. I replaced the OEM starter at 189,000, the OEM water pump shortly after. It has never quit except for a dead battery. Except for belts, brakes, several alternators over 13 years, I have replaced almost nothing. I did rebuild the front recently replacing the CV joints and the inner tie rods. It drives almost as new except for a couple squeaks in the rear I can't seem to locate. But I would drive it to the West Coast in a heartbeat. It doesn't tick, click or smoke.

The other Chevy is sort of a toy--a 1993 Lumina that I have put less than 30,000 miles on in the last 4 years. It is a Z34 that has proven to be reliable, mechanically sound, economical to drive, and just plain FUN. It is my Sunday go-to-meetin' car and it gets babied to death and both cars have always been garaged. The wagon is my "beater" that I drive every day, have my mobile ham rigs in, pull my lawn tractor with, haul lumber in, and even firewood! While Ford seems to be extremely popular, I can't agree that Chevrolets are prone to mechanical failure.

Since 1966, I have owned quite a few from a '61 to the '93 without having ANY recurring failures. The failures I had were with the Fords that had a habit of leaving me to walk back home. I learned to spell Ford backwards (D-river R-eturning On F-oot). LOL! I got extremely pissed at them after the fiasco with the '73 Mustang, and Ford's refusal to honor their tranny warranty. I cussed them out, stormed out the door, and traded down to a '69 Impala just to get rid of it! LOL! Funny, that 4 year old Chevy NEVER left me stranded NOR did it make ignition noise--and that was without doing anything to it.

It's what you get used to, I reckon!

Absolutely never.

This, however, doesn't diminish its utility as a modeling element or a tool to gain insight into how real things work. Real engineers use the concept of pure reactance daily in the development of real things that work.

There are actually two independent claims in the patent, 1 and 13,
although they differ only very slightly from each other, and both deal
with a method of tuning.

I thought the glass mount antenna would extend above the top of the
vehicle. That would cut down on a lot of the RF inside the vehicle right?
I'm not installing any such antenna but I commonly run 15 to 20 Watts on 2
Meters. Mind you I am not cutting down the idea, just curious.

On the contrary, "power flow" is a concept accepted by the IEEE but
not by some on this newsgroup. I find it hard to visualize the power
in a pulse being anywhere except the pulse.

Source record: 178565

I have a question, bear with me. During the Desert Storm War, I 'heard' reports from the ''front'', and they would be by 'satellite phone', and there would be a '''delays in the transmit and receive messages '', maybe lasting a second or two, because the 'repeater' was in space. I am guessing those repeaters were located at about 22,000 miles out. ????. I don't really know what the distance was. Soooooo, with saying all this, my question IS if satellites were placed in space and were used as the cell phones are used today, how high up would they have to be???????????. Or another words how low could the ""repeaters"" be before they did not run in to the problem of ===delay===., and still stay in their orbit.??? (As I look over this question, I see I am not asking the question right, but I hope you ''see'' what I am trying to ask. :) C.

Look at a Smith Chart and observe what impedance that 71 volts is seeing. It is NOT 300 ohms. The reflections have changed the impedance from 300 ohms to 51.5 ohms.

> The impedance discontinuity at the junction is a function of the reflection
> coefficient at the junction. The reflection coefficient is +.707. The 71 v
> is transformed into 122 volts in the 300 ohm line - 50 watts of power.

V/I at the Z0-match is 51.5 ohms and varies from there around a 5.83:1 SWR circle on the Smith Chart.

> An impedance discontinuity always exists at the junction between the two
> transmission lines. The steady state match is a result of rearward voltage
> cancellation that only occurs because the impedance discontinuity always
> exists.

On that we agree. The impedance discontinuity is what makes the Z0-match possible.

> Really??? Like 71 v in a 300 ohm line is equal to 100 watts of power.

I never said that. The 71v doesn't see 300 ohms. The 71v sees 51.5 ohms. With an SWR of 5.83:1, 300 ohms is never seen because 300 ohms is the center of the SWR circle. (Total Voltage)/(Total Current) is NEVER 300 ohms. At the Z0-match, it is 51.5 ohms.

There is another consideration as well: For digital cellular service,
there is a time-delay problem that shows up at around 15 miles from the
cell site. I believe that this is related to the frame rate of the data
packets. Using gain antennas to get greater range would lead to
problems. (Someone more familiar with the intricacies of this problem
may want to elaborate.)

Bill,
MFJ does make ~good~ tuners, but I think Dentron made
some of the ~best~. No matter who makes the tuner, always
use one that's rated much higher than what you think you
need (no such thing as 'over-kill' with tuners).

Same question stated in a slightly different way:

Imagine a transmission line connected to a resistor at one end. At the other end two ac generators of equal volts but opposite phase. Zero power is delivered to the load and each generator delivers zero power.

In the case of light waves, since no power is delivered because of phase cancellation, no power is delivered by the light sources to a load, so no power is delivered by either light source.

A power source delivers power to a load only if the load is accepting power.

A lossless line (or empty space) does not actually "deliver" power unless there is something out there to accept it.

Some folks say that an antenna is "dissipating" the power that it radiates. I believe that the antenna "transfers" power from the transmission line to the 377 ohm transmission line of empty space. The antenna is exactly like a two-port network that may have some actual conventional resistance loss and a 50 ohm to 377 ohm transformer, but most of the RF is (hopefully) "transferred" to space. I prefer the classical idea that power "dissipation" means a conversion of one kind of energy to another kind of energy.

Antenna radio power is "dispersed" in *empty* space but it is still antenna radio power.

Walter-
I have been reading MANY of the posts from MANY different people, and it seems to me that several are posting arguments that are based merely on what they THINK you meant in your earlier publications. This has bothered me, but, as a non-expert, I shut up.

However, I think your post made some re-think their interpretation, which they thought was in keeping with yours. THey seem to be supportive, but are reviewing your position re the conjugate match in view of your recent post.

I Know of few that are not in your corner. I, personally, was taken aback when I tried to order your book, only to find it "withdrawn". THat was quite a while back. I saw the information about the new version on a post from Press (The Wireman), with glee, and told him to put my name at the upper part of his list for distribution.

I know that what you teach works. I am not too sure about the adherance to strick definitions being used in counter arguments. THere seems to be a BIG language problem. As a retired Rocket research and design Engineer, I know that if the steady state analysis doesnt balance, there is something wrong with the formulation. If the transient analysis arrives at the steady state, it may be right, but that is not a guarantee.

Keep in here with us, please.

If your phantom waves with their phantom power really exist
(even though they cannot be proven to exist by any scientific
measurement) what's to keep them from being the cause of
spontaneous human combustion?

Hint for the humor impaired: the posting was less than serious
and was designed to elicit a chuckle.

Charles Dickens, in the nineteenth century, linked it to an
overconsumption of booze. That can't possibly be true, otherwise
San Franciscans would be flaring up all over the place.

I was going to ask that question, but you beat me to it, Cecil. The
answer would go a long way toward providing a physical explanation
of how reflections do their job on a transmission line. It's
pretty easy to show, symbolically, that, in the steady state,
Steve's methods give correct results. Trying to understand the
details of a transient analysis, however, raises the kinds of
questions you just asked. I think we need the services of a
good physicist.

> --
> http://www.mindspring.com/~w6rca

You have to learn to translate. When you read a physicist, like
Feynman, writing about the Poynting Theorem, you have to
substitute the word "power" whenever he writes "energy flux",
and, if you ever have the pleasure of talking to a physicist,
you have to say "energy flux" whenever you want to say "power".
This is reasonable, since physicists have defined power in
relation to work done on a physical object. If they started
talking about the rate of movement of energy into and out of a volume
as power, their students would start asking embarrassing questions.

Roy Lewallen wrote:
"It`s really not hard to do with feedback (an amplifier with a source impedance of zero, or a constant voltage source)."

Yes, but the constant voltage source can only maintain the output voltage constant down to some minimum load impedance. At lower load impedances, it loses control and the voltage droops due to the real internal components` impedance. At very low load impedance, the generator can`t keep the voltage up.

Negative impedance generators exist. One example is used as a telephone repeater. It cancels out some of the line loss. Negative impedance repeaters don`t produce a net gain. Negative impedance generators must be used with positive impedance loads with loss exceeding the negative impedance for stability.

Best regards, Richard Harrison, KB5WZI

That's because no energy is being moved. No movement of energy equals
no power. But a photon already possesses moving energy.

> In the case of light waves, since no power is delivered because of phase
> cancellation, no power is delivered by the light sources to a load, so no power is

This is different. Moving photons possess energy. During atomic annihilation
of two gamma ray photons, a positron and an electron are created indicating
that power is delivered to the load. What happens to a photon if its energy
cannot be delivered? Doesn't the photon have to go somewhere?

> A power source delivers power to a load only if the load is accepting power.

That's true, if a photon doesn't encounter a load it keeps on going. So
where do the photons go when a destructive interference pattern is
established? They seem to disappear. Where did they disappear to?

Tom:

Think of it this way. The phenomenon of rearward wave cancellation in the transmission line (the impedance match) is similar to RF multipath in a real world propagation environment. In the real world environment, a transmitted signal will reflect off of the earth, trees, buildings, towers, etc, etc. At some locations, many of these multipath signals will arrive at or intersect at some point. Clearly, each signal will have different amplitude, phase delay, etc. Each will also have traveling power or energy associated with it. At the point where these signals meet, the net summation of all of these signals may result in a complete cancellation of all signals, hence the multipath fade (wave cancellation). At this multipath fade point, we would not be able to measure the energy contained in any one of the individual signal components but they exist individually, they simply cancel one another for a net zero power at that point. The law of conservation of energy is satisfied because the total power dissipation is equal to the total power delivered - zero. Each of the individual signals has power associated with it, yet we measure none at the multipath point. Does that mean that they don't exist individually or that they are phantom waves? Not at all.

In the transmission line, we have a similar situation except that we are also forcing the waves to travel in the same direction. In the transmission line, there is a transient process of wave reflection and re-reflection at any impedance junction. After a very very short period of time, the net result of this transient behavior is in fact the steady state condition. As stated, all we can measure is the total net sum of the individual transient wave components. That does not mean that they don't exist individually or that they are phantom waves.

The impedance match in the transmission line occurs when the net steady state sum of all these transient waves traveling in the rearward direction combine at a single point (the match point) to a total wave of zero voltage and zero current (multipath). Since we constrain these waves to be traveling in the same direction, the net rearward power flow at all points before of the match point is zero.

The other point to mention is that there are two sources of rearward wave travel at the match point. One occurs from the mismatch that the source wave sees arriving at the match point (rearward wave 1) and the other occurs from the reflected wave arriving at the match point (rearward wave 2). The level of rearward wave 2 is a function of the mismatch seen by the reflected wave when it arrives at the match point. Rearward wave 2 is comprised of numerous transient waves due the multiple wave reflections occurring between the match point and the load. In the steady state, rearward wave 2 is 180 degrees out of phase wrt rearward wave 1 and the net rearward wave is zero.

249. 75M mobile in a Jeep Cherokee - antenna help needed

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-03 00:00:00 UTC
From: "J.T. Johnston" <jt@central-web.com>
Message-ID: <stk35e6lahet6b@corp.supernews.com>
Source record: 178583

I have unsuccessfully tried to run 75M in my Jeep using a Hamstick mounted on the trailer hitch. After managing to get it close to resonance (ha, ha!) by trimming the whip, I put my trusty MFJ tuner in line and made it match the rig. The problem is that nobody can hear me outside of my local area. It is nearly impossible to check into our 75M traffic net in the evenings, unless I move the rig in the house and hook up to the G5RV.

My question is this: Has anyone had any luck with a similar setup? I assume my problem is that the rear of the Jeep is severely distorting my radiation pattern, but if I put the antenna on the roof of the Jeep (obviously the preferred location), the tip would be over 12' off the ground. Though it should stay out of power lines at that height, there are several trees in my neighborhood with which it would not get along.

One other thing, my Jeep also puts out a great deal of RFI on most every band. Most problematic is the fact that one of the frequencies that is strongest in the output frequency of our 2M repeater (147.16). The mobile rig is fine, but I have to turn the HT off when I have it in the Jeep, or the squelch will stay open all of the time.

I welcome any helpful advice.

TNX & 73,
J.T. Johnston, N4ZWV

Steve wrote:
"A "total" re-reflection of this energy does not occur, ever."

It`s hard for me to follow the arguments because I forget which model is being argued. If we have a 50 ohm transmitter (a pox on 51.5 ohms!) connected to a 50 ohm load via 300 ohm twinlead, 1/2 wavelength long, neither the transmitter nor the load will "know" the twinlead is there, if we assume lossless transmission lines.

Your Bird wattmeter won`t measure any reflected power in or out of the 300 ohm twinlead. all the reflections are in the 300 ohm "tuned" line.

Moreover, it is crazy to talk about lossy lines and matching networks when your subject is maximum power transfer. Maximum power transfer is about source and load impedances, only. Any transmission line losses must be lumped with the source or load.

Best regards, Richsard Harrison, KB5WZI

Hi Steve,

I'm missing something here.

You are directly adding the voltages of the reflected signal to the
incident signal, and using that to derive power.

Will you please describe a practical circuit example of where that
would occur?

I'm having trouble getting past that statement.

Cecil--

I have a 100 watt transmitter with a 50 watt AM modulator installed in the PA's B+ line. Following your logic, shouldn't my wattmeter read 150 watts output at 100% modulation? Except it only reads 100. Yet, to replicate the same waveform and power meter reading using my AL-80, it's gotta deliver 400 watts! To me, this proves AM Radio must cause spontaneous human combustion. How else do you explain 100 w + 50 w = 400 w?

Hi Richard,

There is no argument from me as to the steady state conditions in the transmission line system. The issue is what really happens to the reflections when they arrive at the input to the 300 ohm line. Does a total re-reflection really occur? All of this is purely an academic exercise. For steady state design of matching networks, tuners, etc, none of this really matters. As Cecil said, the Smith Chart works great.

Not trying to practice law, but:

That's a crock. Either a patent is issued or it isn't. The Patent Office will not tell you if or when your patent will issue, so "As of tomorrow....." has no meaning. He doesn't know that any more than any of the rest of us.

>Just as a practical matter, if I request a reprint of the above
> published article from the authors today, will they be in violation of
> your patent if they send it to me?

A patent allows you to keep others from making, using or selling your idea. Nothing more. Anyone can write about it, and obtaining a copy isn't unlawful. As a matter of fact, once the patent is issued, it is available from the Patent Office and other places as public knowledge. The purpose of a Patent is to increase the knowledge of a subject. That's why you are reqired to disclose your best method of practicing it at the time of filling.

See a Patent Attorney.

No. You also have to look at the voltage. If the voltage is in quadrature with (i.e. 90 degrees with respect to) the current, no power is flowing. This is the situation when the current is flowing through a pure reactance. The power being delivered is V * I * cos(theta) where theta is the phase angle between the voltage and current.

I am somewhat curious as to how you can patent a fractal antenna, particularly when you have stated here in the newsgroup and in your white paper that Yagi's are fractals as well. In fact, have you not stated that any random antenna is a fractal? How did you get around the "prior art"?

Hi Tom:

I'm not sure where the issue is above so if I don't answer your question directly, please let me know. I know you are on the ball technically so please don't take this as a lecture.

First, I used 100 watts in the discussion above because that was the net steady state forward power delivered to the match point in Cecil's example. Clearly, in Cecil's example, the steady state forward power in the 300 ohm line is not 400 watts, it is 200 watts. My discussion differs from Cecil's

in that I state that the forward source power in the 300 ohm line is 50 watts, not 100 watts and that the re-reflected power is 50 watts not 100 watts. 50 watts, added in phase with 50 watts is 200 watts. I assume this is where the problem is, ie. how does 50 watts + 50 watts equal 200 watts?

In the transmission line system, multiple forward traveling voltages (driving and re-reflected) simply add as series complex voltages. VFtotal = VF1 + VF2 where both are complex phasors that add as vectors in Cartesian coordinates. The same applies for rearward traveling voltages. The TOTAL voltage at any single point on the transmission line is equal to the total forward voltage + the total rearward voltage. The power contained in any one forward voltage wave is equal to |VF|^2 / ZO (ZO is resistive). The power contained in the total forward wave is equal to |VFtotal|^2 / ZO. When the voltages are in-phase, the total voltage will double (VF1 = VF2) and the total power will go up by a factor of 4.

From a practical circuit standpoint, connect a transmitter to a matched load through some length of cable. Set the forward power in the transmission line to 100 watts. If there are truly no reflections on the transmission line the rearward traveling power will be zero and the total voltage at any point on the line will be the forward traveling voltage. This is also true at the matched load. Measure the voltage across the matched load. Now increase the total forward power to 400 watts. Measure the voltage across the matched load again. I'm assuming the phase properties of the transmitter are linear with power. The voltage magnitude should double. I'm not sure as to the accuracy of the wattmeter re: the voltmeter.

Another way to think of this is connecting batteries in series across a resistor. Connect a 12 volt battery across 12 ohm resistor, the power dissipation is 12 watts. Now connect two batteries in series, should the power dissipation be 24 watts? No, it is 48 watts.

Hummmm, to me, any antenna that is self similar, such as a dipole,
bowtie, yagi, log periodic, etc, ALL are a form of a fractal. IE: All
have a mirror image from one side to the other. We have been stealing
fractal designs for years. And I for one am not going to stop. MK

264. Cell Band Beam Antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-03 00:00:00 UTC
From: stoskopf@tri.NET
Message-ID: <39DA23D1.30FF65B7@tri.net>
Source record: 178598

40 years ago I worked for a guy that serviced oil field 2 way equipment. Scattered on hills around the countryside were yagis on sticks of oilfield pipe stuck in the ground. Most of the gear was "Hi Band", 170 MHz?. Most of the offices were in Great Bend or Russell. Just about anyone could drive up, hook the hunk of coax to the back of their GE or Motorola tube type boxes and get a quick connect to their office.

Also, when the various groups would have a field meeting, we would drive over. They all left the keys in their vehicles. We would check one transmitter freq with the Lampkin (sp) freq meter and then key it as we adjusted the other receivers AFC to that rig. Everyone in the center of Kansas was at least on one freq!

As always in the oilfield: Do something (even) if you do it wrong.

> Except it only reads 100.

Are you sure?

An AM transmitter with a carrier output of 100 watts will reach a peak
instantaneous output power of 400 watts during modulation peaks.
Assuming the modulation is a single tone, the average output power (at
100% modulation depth) will be 150 watts, 100 watts in the carrier and
25 each in the upper and lower sideband.

>Yet, to replicate the same
> waveform and power meter reading using my AL-80, it's gotta deliver 400 watts!

Right, 400 watts PEP and 150 watts average.

I'd call it more of a slight incongruity than a wide gap. I don't think we really want to consider engineering to be at odds with physics. ;-)

> In RF engineering and power engineering the mere
> movement of electrical energy past a point is defined as power
> with no work required.

The need was for some electrical engineers to be able to understand how "power" could be generated at one end of a transmission line, converted and utilized at the other end of the transmission line without "moving" between points. It's actually quite easy to understand when viewed from the standpoint of energy.

> And the Power Flow Vector is defined at
> a boundary.

Yes. However the types of boundaries to which this may be applied are also well defined, although in some cases, not well understood. The boundary at which the flow vector is defined is assumed to be one at which energy is transformed. Since energy is almost invariably conveyed for the purpose of converting it to another form, this is a fair assumption.

Since the numbers work out, it makes little difference whether we call it a flow of power, or whether we call it a flow of energy. It is simply a matter of convenience, depending on the application, whether we must think of power strictly in terms of the rate of doing work or not. It seems for most thermo and mechanics problems it is more useful to view power as a rate of doing work. For electrical problems it is more convenient to consider power to be the rate of flow of energy with the assumption that something in the closed circuit eventually transfers that energy to another form.

The only point I wanted to dispute here Cecil was that you implied that Gary was incorrect in his comments regarding these definitions. That is not a fair or accurate characterization.

VE9SRB wrote:
> We disagree as to how the steady state conditions are reached.

No we don't, Steve. We agree on the transient conditions. What we disagree on is the nature of the steady-state condition. You believe in phantom voltages, phantom currents, and phantom powers. I say if they are undetectable, they don't exist. You are appealing to Faith-in-the-Unmeasurable to try to prove your point. I put my faith in the measuring equipment. IMO, the only place your phantom signals exist is in your mind. You are essentially trying to keep two glasses of water separate while mixing them together. You simply cannot have it both ways. They cannot be both mixed and unmixed at the same time.

> theory.

Given A + B = C, you are saying that B + C = D, and that is true but completely irrelevant to reality. Adding a cause to an effect is just ridiculous.

> Cecil, you're misquoting me again. I never said hook up two IC-706's and
> you would get 400 watts.

I'm pulling your leg, Steve, but you did say that you could get 400w out of two 100w waves.

> The *net* steady state power delivered to the match point is 100 watts.
> There is a big difference between the *net* steady state power delivered to
> the match point and the *forward* source power delivered to the match point.

If there are no reflections, net and forward are equal.

> There is no doubly-phantom power in my description.

Of course there is, Steve. When coherent V1+V2=0 and I1+I2=0, power equals zero. You are saying power equals V1*I1 + V2*I2 and that's two terms of phantom power. (I left out phase to simplify.)

> The physical impedances at the junction never changes.

The physical impedance of a stub never changes either but that doesn't prohibit us from making extensive use of its virtual impedance. You simply cannot have it both ways, Steve. If what you say is true, stubs wouldn't work but we know they do. If stubs can have a virtual impedance,

then so can a Z0-match, which is just a stub with a load instead of a short or open. A 1/4WL shorted stub presents Z0 initially during transient buildup to steady state. After the stub reflections achieve steady-state, it presents a virtual open circuit. That is no different in concept to the operation of a Z0-match.

> Your statement above is incorrect because it would require that a total
> re-reflection of the reflected power occur at the impedance junction.

Power is a *scalar* associated with coherent in-phase voltages and currents. All that is required is an interference pattern which, like light waves, causes one region to be "darker" and another region to be "lighter". When two coherent voltages and/or currents interfere with each other, the two associated powers don't interfere because there is only ever one total power.

> As for the virtual short circuit, let's review this concept and look at
> another example.

I am not supporting a virtual short circuit and have not used the concept in these postings. I am supporting an interference pattern between two sets of coherent reflected waves that builds up to steady state conditions that can be measured and verified.

The interference patterns resulting from complimentary sets of coherent waves certainly remind me of interference of light waves. It simply becomes darker in one place while becoming lighter in another place.

Luck has nothing to do with it. Your 75m hamstick is about 0.3%
efficient - radiating about 1/3 watt for every 100 watts put
into it.

> I
> assume my problem is that the rear of the Jeep is severely distorting my
> radiation pattern, ...

Not distorting - attenuating. Forget the hamstick for 75m operation.
You need a bugcatcher or screwdriver, preferably with a top hat.

Hamsticks work reasonably well on 14MHz and higher but they are absolute
dogs on 75m.

Light does not annihilate. Matter and anti-matter annihilate. In a scenario where two coherent beams of parallel light cross paths at a point at which they are out of phase, the area of intersection would appear not to be illuminated. The light beams would each then continue to propagate unperterbed on their respective trajectories. But I expect you knew all that. ;-)

#1. A bumper mount is about the worst place to mount the antenna. You
have quite a bit of coupling to the body of the jeep most likely, which
will kill the antenna dead, and also the highest amount of earth loss.
If you use a bumper mount you want the coil as high as possible.
"actually a good idea anywhere for 80m". How tall is the antenna in
itself including the stinger? What I would do in that case is completely
butcher the hamstick and add a much wider loading coil, but you may not
want to do that. You might consider using a 40m stick and add a longer
whip to it to resonate. I've never tried this for 40 to 80 to see the
length of stinger needed, but in the case of the 20 to 40 stick I use, I
need 3 ft to tune a 20 stick to 40. I would use the longest stinger you
can get away with, and if the antenna comes up high in freq still, add a
few turns to the stick in a place where you can easily splice into the
wires, but as high on the stick as possible. Or better yet, do it as I
do, and make a big loading coil to tune the stick and do away with all
the narrow tight windings. In effect a plastic bugcatcher. The 40 to 80
ant will be much more efficient on 80 than the 80 stick will be on 80.
The big coil version will in effect equal the bugcatcher with the same
size coil. And using the longest whip you can will let you hit tress
with no problem as long as your mount is strong. The whip will just slap
off of them, and the stick flexes also. Really flexible. 12 ft off the
ground is legal here in TX. We can go to 13.6 ft I think.

Is this transmit or receive? Sounds like you need better grounding in the jeep. Ground all metal together with strap. Sounds like the ground conection to the bumper mount is bad. MK

I don't think that's true, Jim. From the IEEE dictionary, "The integral
of the (instantaneous Poynting vector) over a surface is the instantaneous
electromagnetic power flow through the surface." Sounds like one could
define the surface in free space if one so desired.

Slight correction. In matter/antimatter annihilation, an electron and a positron are converted to two 511 KeV (rest mass of the electron) gamma rays with equal but opposite momentum. Photons don't annihilate.

>transmitter are linear with power. The voltage magnitude should double.

>I'm not sure as to the accuracy of the wattmeter re: the voltmeter.

I don't have a problem with the voltage doubling when the generator power is increased to 400 watts and the impedances haven't changed.

What I need to know is how I can convert 100 watts of source power into 400 watts of actual power using a phase-coherent source. (That will keep two non-coherent generators of 100 watts effective power from being combined to produce a power level that varies from zero to 400 watts PEP out of the discussion.)

>Another way to think of this is connecting batteries in series across a
>resistor. Connect a 12 volt battery across 12 ohm resistor, the power
>dissipation is 12 watts. Now connect two batteries in series, should the
>power dissipation be 24 watts? No, it is 48 watts.

Only when the currents also double, and now the power from each battery is 200 watts. You have changed the source power.

You claimed, if I'm not mistaken, a single 100 watt transmitter could produce 400 watts of power at multiple points in the system...none of which were described to be VAR power measurements.

Let me ask my original question again:

Can you give me an example of how, by changing only the line match, I can cause the voltages to double and current to double at any single point in the line while they remain in-phase (so power is multiplied by four) WITHOUT doubling the power of the generator?

I want to build a system to prove you are correct. Can you help me build one?

You're right but I have an excuse. From my physic's book:

"This equivalent, for the electron, is directly observed in connection
with annihilation and creation of electrons and positrons ..."

A non-careful reader might mistakenly infer that electrons
and positrons are the result of annihilation.

286. Vertical HF antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-03 00:00:00 UTC
From: littlejohn <littlejohn@planet-interkom.de>
Message-ID: <8rc6gn$1jej$1@news.okay.net>
Source record: 178654

Due to restrictions I am planning to install a multiband HF vertical groundplane (3,5 - 28 MHz). I don't expect any problems on the higher bands, but I do need some tips concerning a grounding system for 80 Meters.. I realize a vertical is not the ideal solution, but if you want to get on the air, you'll try anything !!!

Thanks in advance,

de DL1HWX -- John

>Go with a Ford and get the noise
>or go with a chevy and get mechanical problems(that should get a rise).

At the moment, my '78 GMC pickup has neither -- only a few holes in the floor.
Nothin' a few hours with a welder won't take care of, though. :-)

Walt, I cannot imagine anyone taking offense at what you said. I think the people may have felt that you were certainly an authority on the topic and, rather than risk being caught saying something wrong, they decided to let you speak. :-) Besides, the thread had run on for quite a while; it was probably about due to close. :-)

Tom:

If you check through my previous posts you will see that I indicate that the mechanism for re-reflection of the waves arriving back at the match point is simply the impedance seen at the match point by the reflected waves. This info was detailed in the previous posts.

Doesn't the fact that current is flowing past the measure point make it prima facie evidence that power is being consumed downstream? If not, no current would flow.

You might want to look into chain link fence top rail tubing. It's about 1.75 inches diameter, comes in 20 foot lengths, swages together on the ends and seems considerably tougher than EMT. It's also cheap. You could get 5 pieces, cut one and have two 30 ft masts.
I've used it a few times for short masts with good results. I believe that Tom W8JI had plans a year or so ago to to use it for some guyed vertical antenna phased elements. Haven't heard how that project turned out.

Too bad "consume" is not in the IEEE dictionary. To me, the word
"consume" would conote being "used up" so a lossless antenna radiating
in free space would not "consume" any power. What definition of "consume"
did you have in mind?

Too bad your explanation requires a religious-like faith in phantom
waves, the existence of which you cannot prove. I've been thinking:
Maybe your phantom waves with their phantom powers are responsible
for spontaneous human combustion.

On a related note: What happens to the EM energy when two coherent
light waves are phased such that annihilation occurs? How is energy
conserved? Where does the energy go and in what direction(s)?

Check onto the vertical dipole type antennas like MFJ sells that don't require a ground plane. If you do go with this type such as an 18AVT/WB or a modern equivlent, it will work with a little a 1 ground wire which will work like a counter poise versus a ground image. You will have a lobe in the direction it goes in, but it will work, but don't expect to be a top contender in a contest. Try to make it a straight a possible, "folding" at the far end as little as posible. Also consider a "ground ring" verses a ground rod. This sould give you a better ground connection. These are availble through commerical electrical suppliers and the 2 sizes i know of are 6' and 8' in diameter.

Cecil, you know I *never* said the steady state wasn't the truth. We
disagree as to how the steady state conditions are reached. Please do not
start to misquote me or incorrectly state my technical position.

>
> Well then, that's obviously not what you had in mind when you said
> 100w + 100w = 400w. Please tell me how to hook up two IC-706s to
> get that 400w you promised.
>

Cecil, you're misquoting me again. I never said hook up two IC-706's and
you would get 400 watts.

In the 300 ohm transmission line, a forward source power of 100 watts has a
forward voltage of 173.2 volts. A re-reflected power of 100 watts would
also have a forward voltage of 173.2 volts. If these voltages are in phase,
the total forward voltage would be 346.4 volts and the total forward power
would be 400 watts. These concepts are fundamental to basic circuit theory.
Vtotal = V1 + V2. Power = |Vtotal|^2 / Z (Z being a pure resistance). If
you double the voltage across any given resistance, the power delivered to
that resistance will increase by a factor of 4. No magic, no perpetual
motion machines.

The *net* steady state power delivered to the match point is 100 watts.
There is a big difference between the *net* steady state power delivered to
the match point and the *forward* source power delivered to the match point.

In the example you presented, I specifically said that the *forward* source
power in the 300 ohm line was 50 watts (122.47 volts) and the re-reflected
power at the match point was 50 watts (122.47 volts). These two forward
voltages add to a total forward voltage of 244.94 volts for a total forward
power of 200 watts, the correct steady state solution, consistent with basic
circuit theory and basic transmission line theory.

>
> It can detect reflected power, Steve, and there ain't none on the coax.
> Power cannot exist when voltage and current are zero. You are asking us
> to reject something dubbed a "virtual short" in favor of something that
> can be described as phantom voltages, phantom currents, and doubly-phantom

> powers. Given the "virtual short" concept could be improved but I don't
> think doubly-phantom power is the way to do it.
>

All I said was that two rearward traveling waves cancel one another to a net rearward traveling wave of 0 volts and 0 current. In this case, there is no *net* rearward power flow. The SWR meter reads *net* power flow. There are no inconsistencies in my statements. There is no doubly-phantom power in my description.

>
> Seems to me the following is all we need to say: The reflections that
> exist on the coax during the transient buildup to steady-state, are
> eventually completely canceled by a complimentary set of reflections
> from the load.
>

This is somewhat correct.

>Since the steady-state result is no reflected energy on
> the coax, all energy incident upon the Z0-match is forced toward the
> load since there is no other place for it to go and it cannot stand still.

There is rearward energy incident at the ZO match. Actually at the junction between the 51.5 ohm and 300 ohm lines. The ZO match is a steady condition resulting from rearward wave cancellation. The physical impedances at the junction never changes. When the rearward energy arrives at the impedance junction, there is a partial re-reflection of power in the 300 ohm line (50 watts in the example) and a partial transmission of power into the 51.5 ohm line (50 watts in the example). The 50 watts of re-reflected power combines with the forward driving power (50 watts) resulting in a total forward power of 200 watts. The 50 watts of power delivered into the 51.5 ohm line is 180 degrees out of phase with the 50 watts reflected at the junction such that the two combine to a net rearward power of 0 watts (wave cancellation) and the steady state match.

Your statement above is incorrect because it would require that a total re-reflection of the reflected power occur at the impedance junction. It does not. It is also incorrect because it would require 100 watts of forward power plus 100 watts of re-reflected forward power to equal 200 watts of forward power. Power "addition" in this manner is inconsistent with basic circuit theory.

As for the virtual short circuit, let's review this concept and look at another example. When a steady state impedance match exists at the junction between the 51.5 ohm and the 300 ohm line, a virtual short circuit is said to be created, which effectively causes a *total* re-reflection of all reflected power in the 300 ohm transmission line. This re-reflected power (100 watts) then adds in-phase with the forward source power delivered to the match point (100 watts) and the two in-phase powers add to a total forward power of 200 watts. (I do not believe any of this to be correct)

Now its my turn to define an example. Let's look at the case where a steady state impedance match does not exist at the impedance junction between the 51.5 ohm line and the 300 ohm line. Specifically, let's look at the relationship between all steady state forward and rearward powers at the impedance junction between the 51.5 ohm and the 300 ohm line.

Let's set the load impedance to 51.5 + j51.5 ohms. In this case, the *steady state* conditions are as follows:

The steady state input impedance at the junction is 51.5 +j51.5 ohms. An impedance mismatch exists at the junction with an SWR of 2.62:1

The steady state forward power in the 51.5 ohm line is 100 watts. The reflected power in the 51.5 ohm line is 20 watts. The *net* steady state power delivered to the 300 ohm line is 80 watts.

The steady state forward power in the 300 ohm line is 163.37 watts. The reflected power in the 300 ohm line is 83.37 watts. The steady state power delivered to the 300 ohm line and the load is 80 watts.

Now, what do we learn by looking at *only* the steady state power levels? We know that the source delivers a net steady state power to the 300 ohm line of 80 watts. We know that the forward power in the 300 ohm line is 163.37 watts and the reflected power is 83.37 watts. What conclusions could I reach with *only* these measurements? I could conclude that a virtual short circuit still exists. I could conclude that the 83.37 watts of reflected power is totally re-reflected at the junction and "adds" to the delivered source power of 80 watts such that the total forward power in the 300 ohm line is 163.37 watts. But an impedance match does not exist at the junction and the re-reflected power is not in-phase with the forward source power. Do you see that the steady state power levels do not provide sufficient information to reach any conclusion without further analysis?

The truth is, that in *any* transmission line system matched or mismatched, the net steady state power delivered to the system is equal to the forward power in the system minus the reflected power in the system. However, it is incorrect to reach the conclusion that a total power re-reflection occurs. Without further analysis, the steady state power levels do not provide enough information to describe the wave reflection process occurring at the junction.

Now, let's look at this example from my perspective.

The forward voltage of 71.76 volts (100 watts) arrives at the impedance junction between the 51.5 ohm line and the 300 ohm line sees a reflection coefficient of +0.707. There is a reflected voltage equal to +50.73 volts developed in the 51.5 ohm line. This is equivalent to 50 watts of reflected power in the 51.5 ohm line (remember this for later). The total voltage developed at the impedance junction is equal to 122.49 volts. This is the forward source voltage delivered into the 300 ohm line. The forward source power delivered into the 300 ohm line is equal to 50 watts.

Now, let's jump to the steady state. The steady state rearward reflected voltage in the 300 ohm line is equal to -124.16 + j97.96 volts (|V| = 158.15

volts, Phase = 141.73 deg). This equals a reflected power of 83.37 watts in the 300 ohm line. According to basic transmission line theory, the level of voltage re-reflection at any impedance junction is found through the reflection coefficient. In this case, the reflection coefficient is equal to -0.707. Therefore, the re-reflected voltage at the impedance junction is equal to 87.78 - j69.26 volts (|V| = 111.81 volts, Phase = -38.27 deg). This equates to a re-reflected power of 41.67 watts in the 300 ohm line.

Now, the *total* steady state forward voltage in the 300 ohm line is equal to the source forward voltage plus the re-reflected voltage. The total forward voltage is equal to 122.49 volts + (87.78 - j69.26 volts) = 210.27 - j69.26 volts (|V| = 211.39 volts, Phase = -18.23 deg). This total forward voltage translates into a total forward power of 163.37 watts in the 300 ohm line. Correct steady state solution.

Now what else happens at the impedance junction? The reflected wave arriving at the impedance junction causes some level of voltage (power) to be transmitted back into the 51.5 ohm line. The total voltage transmitted back into the 51.5 ohm is equal to the sum of the reflected and re-reflected voltages. The total voltage transmitted back into the 51.5 ohm line is equal to -36.38 +j28.71 volts (41.7 watts). This rearward voltage adds to the reflected voltages created by the source voltage (+50.73 volts). Therefore, the total rearward voltage in the 51.5 ohm transmission line is equal to 14.35 + j28.71 volts (|V| = 32.09 volts, Phase = 63.43 deg). This equates to a total steady state rearward power of 20 watts in the 51.5 ohm line. Correct steady state solution.

Let's look at this example using the formula presented previously for power addition in a transmission line:

Ptotal = P1 + P2 + 2 sqrt(P1) sqrt(P2) cos(theta), where theta is the phase angle difference between the voltages V1 and V2.

The source power delivered to the 300 ohm line is 50 watts. The re-reflected power in the 300 ohm line is 41.67 watts. The phase angle difference between V1 and V2 is -38.274 deg.

Ptotal forward in 300 ohm line = 50.02 + 41.669 + 2 (7.0725) (6.4551) (0.7851) = 163.37 watts

The reflected power in the 51.5 ohm line due to the 100 watts of source power is 50 watts. The rearward power in the 51.5 line due to the reflected power of 83.37 watts arriving at the junction is 41.7 watts. The phase angle difference between the two is 141.73 degrees.

Ptotal rearward in 51.5 ohm line = 49.98 + 41.702 + 2 (7.0697) (6.4577) (-0.7851) = 20 watts

Clearly, this analysis is more complex and detailed than looking at the steady state power levels and concluding that a virtual short circuit exists or doesn't exist. However, this analysis is necessary in order to describe the correct behavior of wave transmission, reflection and re-reflection in a transmission line system. A total re-reflection of power is simply not

occurring at the impedance junction, matched or mismatched.

Cecil: At this point, I will concede that last word to you. It's been fun but I know that we will always continue to disagree so it makes no sense to continue to state the same opinions over and over.

" On the receiving end, the chakras or nerves of the parasympathetic nervous network respond by stimulating or blocking hormone uptake to the brain - the brain's response at the sympathetic junction of the sensory neurons. Here through enzyme action, a release on the transmitter sites takes place at the neurons. The transmitters are either excitatory or inhibitory, depending on the type of transmission release. Such synapses have been distinguished morphologically in the electron microscope; excitatory synapses tend to have round vesicles and inhibitory synapses tend to have flattened vesicles. Thus you can easily see how Shape Energy in biochemical transmission and reception is extremely critical and effective. "

Makes perfect sense to me, as the nerve network is a fractal system...

> especially so without so labelling it, as I mentioned.

Sure, inaccuracies exist, and engineering methods usually have one or more approximations. I just think that an author should strive to be as technically accurate as possible. And like you say, if a presentation is inaccurate or approximate, it should be clearly labeled that way.

> If you think his doing so "dumbed down" ham radio you evidently
never
> suffered much exposure to all the misinformation within the hobby that

> before "Reflections", and is still way too predominant.

No, I just would not want to see dumbing down become a policy of an author. I would rather see Walt be accurate yet informative. Tough job, no doubt.

By criticizing, I'm not saying Reflections is worthless. There's a wealth of info in there. But sometimes by criticizing, things get improved. That's good for everybody.

> Did Walt make a mistake in using the Conjugate Match theorm as he did? Not

Well, certainly those details could be added to the book. The amateur could skip over them, but the engineer might find them very valuable.

Scott,

I used to live in San Jose and had a 40" tower. A ham friend of mine in San Jose just completed a tower by permit in South San Jose and he indicated a 65 foot limit. You should go and check with your building inspectors / planning department...

By the way, we work for the same company...and we both work in San Jose...feel free to email me or call me if you have questions about obtaining permits...I've done it 3-4 times and it's not that much of a problem.

No question that something is very much amiss with Roadrunner this evening. It's taking an average of 90 seconds to download a single email message. Ditto for newsgroup messages and web pages. I've been contacted by users at two commercial RR insstallations which I administer, reporting the same problems.

I can't get through on either the local or 1-800 RR numbers - so I hope that somebody in tech support is reading this.

I smell another system-wide crash coming on... wonder if this message will even "take" on the news server?

I thought you said steady-state wasn't the truth. How can you reject
steady-state and like the Smith Chart?

> In this case Cecil, you would be driving the 50 ohm load with two equal
> voltages in parallel.

Well then, that's obviously not what you had in mind when you said
100w + 100w = 400w. Please tell me how to hook up two IC-706s to
get that 400w you promised.

> I was unaware that the SWR meter could independently detect two steady state
> powers traveling in the same direction simultaneously and then present a
> relative measure of both via the meter reading.

It can detect reflected power, Steve, and there ain't none on the coax.
Power cannot exist when voltage and current are zero. You are asking us
to reject something dubbed a "virtual short" in favor of something that
can be described as phantom voltages, phantom currents, and doubly-phantom
powers. Given the "virtual short" concept could be improved but I don't
think doubly-phantom power is the way to do it.

Seems to me the following is all we need to say: The reflections that
exist on the coax during the transient buildup to steady-state, are
eventually completely canceled by a complimentary set of reflections
from the load. Since the steady-state result is no reflected energy on
the coax, all energy incident upon the Z0-match is forced toward the
load since there is no other place for it to go and it cannot stand still.
(I have non-glare lenses in my glasses that act the same way.)

Nowhere in my Antenna Book does it say zero current can cause fields
that cancel. Try running those differential currents through the same
single wire and see what happens.

> Because it's based on *standard* transmission line theory.

Please give a reference that says that zero current and zero voltage
can generate phantom power and phantom fields.

The way we used to determine RMS power of an audio amplifier was to measure the peak sinewave output voltage into the rated load just before the onset of clipping, multiply the peak voltage by .707, square that, and then divide by the load impedence. By citing the RMS value, one would be able to differentiate from those who may have been using peak power values in order to make their power figure higher for the sales literature.

The idea of trying to adopt a standard way of determining power output was to avoid pitfalls similar to those currently enjoyed in the antenna market, e.g. 12 dB gain, 3 element Yagis.

Rick, K1BQT wrote:
"Shouldn`t this be a cut-and-dried issue after 75 years?"

Yes, and it is. The FCC specifies a measured common point impedance, and the reading of an r-f ammeter at this point, as how the power output of the a-m broadcast station shall be determined. The rules and test questions specify that a current increase in the r-f common point reading of 22.5% indicates 100% modulation.

A separate modulation monitor is required to improve monitoring. There is a carrier level set meter which calibrates the monitor and also indicates non-linear modulation as the carrier level set meter will dodge on non-linear peaks. The range of the percent modulation meter starts at zero and thus gives a much better indication of modulation than a current meter which only increases by 22.5%. The meter action is much faster than that of a thermal r-f ammeter.
Also, the modulation monitor is usually equipped with an alarm for peaks exceeding 100%. Usually this is a flashing lamp and sometimes this is augmented with an audible alarm. What`s more, the modulation monitor doesnt have to even be located on the station site. It can be almost anywhere the station can be received well.

Best regards, Richard Harrison, KB5WZI

"I`ve seen a number of these instruments cross my bench for
calibration."

Yes, I`ve worked with models from several manufacturers too. Some if not all allow you to select positive or negative modulation peak monitoring. As pricey as these instruments tend to be, they should monitor both peaks simultaneously and allow you to alarm either or both peaks for near 100% or more modulation.
But all I`ve seen were positive or negative peak detector, you choose which and what level to alarm.

Source record: 178376

Gentlemen of the newsgroup:

I am today announcing my patent-pending new invention, the Proctenna. This revolutionary device, while amazingly successful, unfortunately cannot be described in detail due to it's current pending status.

Briefly, the device is based on a 23" flexible tube, similar to smooth electrical flexible conduit, with a special conical tip, which acts as an insertion waveguide. The antenna operates on the principle of biofeedback, is self tuning, and also self grounding, as long as the operator stands barefoot in moist soil. In tests, the device has generated much excitement among our users, bringing some, in fact, to tears!

I will make additional details available about this thoroughly proven and documented device once the US Patent and Trademark Office has given it their scholarly and most critical review. The patent application was submitted last Tuesday, and they have given me every assurance that the patent will be granted by the end of this week.

Stay tuned for some illuminating news over the next few weeks!

Yours truly,

Harding D. Beezler, PhD.
Creator of Proctenna

Actually, the documentation says that the 8-9' whip will only tune down to 40 meters. Needs a 23' length to tune 75 meters. I'm gonna take about 16-17' of antenna wire and put an insulator on one end of it and a alligator clip on the other. When I'm stationary at the lake, etc, I'll throw the end of the wire up over a tree limb and operate 75 meters that way.

I'm a bit concerned anyway bout the CD grade mount I bought. There probably isn't 1/8" of insulation between the stud and ground in that mount. Probably will have to break down and buy the whip ICOM sells for use with this tuner.

Taking orders for the W4JLE fractal antenna.
This antenna is similar to an M12 type design. This unpatented antenna can be yours for a small investment of $431.27 Plus shipping and handling.

Remember in Popeye, inspite of all the bad things people said about Brutus, Olive Oil kept saying "But he's large". In this case you can substitute "But it's small".

If enough interest exists, we will start production and shipment of this antenna oddity and remember "But it's small"

Performance and EZNEC files available on a number of websites near you...

336. Aluminum for antennas?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-04 00:00:00 UTC
From: John Harper <ae5x@qsl.net>
Message-ID: <39DB63BF.5BE8D590@qsl.net>
Source record: 178421

Good morning all,

After years of reading about home-made Yagis, verticals, quads, etc that use aluminum tubing, I finally decided to build something (2 el vert for 80m) myself. A lot of articles in QST and various books call for using 12' sections of aluminum with diameters ranging from 1-1/4" to 1/2" that will "telescope" into each other in order to achieve the desired length. I went to Home Depot then Loews and then a local hardware store and not only do they not have it, they don't have any idea where I can get my hands on even a 10' length of aluminum. Who sells this stuff?! Seems to be as scarce as hen's teeth around here.

Thanks & 73,

Andy,
If the antenna was made for mobile use then I would
expect that without a ground plane of some type, it isn't
going to work very well. Providing a ground plane (radials)
shouldn't be that difficult, why not do that? Done properly,
it should work 'better' than the 'rubber duck'.

This is really amazing. In the late '60's and early '70's I lived in an apartment very close to a moderately busy street, and my main antenna was a ground mounted vertical. Most cars going by didn't bother me, but sometimes I could hear ignition noise from one a block away, and it was overpowering as it went by. These noisemakers were invariably Fords -- just like Jerry said. I guess some things never change.

You are missing the 50 watts added by the modulator. 100w + 50w = 150w
Remember the conservation of energy principle?

The rule-of-thumb that phone companies use is that you need to limit the total round-trip delay to under 200 milliseconds to avoid annoying users. A circuit through a geosynchronous satellite at 22,300 miles altitude presents a 90,000 mile round trip, or not quite 500 milliseconds of round-trip delay at the 186,000 mile/second speed of light. If you want to keep the delay under the 200 ms budget the satellites will need to be kept under 9,000 miles altitude.

Once you've dropped below the 22,300 mile altitude, however, the satillites are no longer geosynchronous and instead move with respect to the earth's surface. This means that you'll now need a lot of satellites to ensure continuous coverage of any particular point on the surface, with the number of satellites being mostly independent of the altitude they are at, so you might as well drop the satellites a lot lower, say under 1,000 miles, as this will minimize both the cost of launching the satellites and the gain requirements for the phones.

The economics of doing this haven't been very attractive compared to ground-based systems, however. If you search the Motorola web site for "Iridium" you'll find straggling references to an attempt to do this, including pictures of the phones. Iridium had about 60 satellites up several hundred miles. The company went bankrupt, and they started de-orbiting the satellites early this year. Globalstar (www.globalstar.com) is another company taking a shot at this, with 48 satellites. Teledesic (www.teledesic.com) is planning to launch 288 satellites, 900 miles up, to provide bigger bandwidth data services. We'll see how that goes.

342. Virtual Short Circuits and Total Re-reflection

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-04 00:00:00 UTC
From: Walter Maxwell <w2du@journey.com>
Message-ID: <bAHC5.4126$mC.261654@monger.newsread.com>
Source record: 178427

From reading recent posts on this news group, it is evident that serious misconceptions still prevail concerning virtual open and short circuits on transmission lines, and whether total re-reflection of power can occur in impedance matching operations. My position is that both of these concepts are valid, and are the basis for the statements appearing in my book 'Reflections' concerning impedance matching.

Some posters on the NG deny that these concepts are valid, and therefore condemn Reflections for propagating incorrect information. An article has been published so stating.

So I propose a simple transmission-line problem, with five questions for the group's consideration to stimulate thinking that could ultimately reverse the position of the naysayers. I'm confident that everyone in the group will answer the questions correctly. However, if they answer the questions correctly, it will prove they consider the concepts of virtual short circuits and total re-reflection valid. The naysayers who answer correctly must merely rethink the semantics of the problem.

The setup for the problem consists of a lossless transmission line of any length, with a characteristic impedance Z0 =1.0, terminated in a purely resistive load, R = Z0, and fed with continuous voltage V = 1.0 of frequency f. All energy available from the source is absorbed by the load. Thus, the initial current flowing in the load is 1.0 amp. We now connect a lossless transmission-line stub in shunt with the main transmission line at any place along the line. The stub can be either a l /2 line at frequency f, short-circuited at the far end, or a l /4 line at frequency f, open-circuited at the far end.

Now for questions concerning what occurs after the stub is connected.

1. What is the amount of current now flowing in the load?

1.. 2.0 amp
2.. 1.0 amp
3.. 0.5 amp
4.. 0.0 amp
5.. None of the above
2. What is the line voltage at the stub point?

1.. 2.0 volts
2.. 1.0 volt
3.. 0.5 volts
4.. 0.0 volts
5.. None of the above
3. What is the line voltage l /4 toward the source from the stub point?

1.. 2.0 volts
2.. 1.0 volt
3.. 0.5 volts
4.. 0.0 volts

5.. None of the above
4. What is the line voltage l /2 toward the source from the stub point?

1.. 2.0 volts
2.. 1.0 volt
3.. 0.5 volts
4.. 0.0 volts
5.. None of the above
5. What occurs on the line at the stub point?

1.. Voltage and current are totally transmitted past the stub point and their energies are totally absorbed in the load.
2.. Voltage and current are partially transmitted past the stub point and partially reflected back toward the source.
3.. Voltage and current are totally reflected back toward the source.
D. None of the above

This is one of my problems with Steve's analysis which requires phantom reflected power to exist where it cannot be detected. We are asked to have faith in its existence. If you have to chose between phantom undetectable reflected power and a virtual short, which would you choose? :-)

RE reflections: Let's say a 71v/1.4a generated wave is incident to a 51.5/300 ohm impedance bump. Let's say the incident waves are at zero degrees. Since this is an impedance step up, the reflected voltage will stay at zero degrees but the reflected current will shift to 180 degrees. This reflected wave will contain 50w of reflected power. Assuming a 1/2WL 300 ohm line with a 51.5 ohm load, the returning reflected power will cause the originally existing reflected power at the 51.5/300 ohm impedance bump to cease to exist because of destructive interference. Since there is no reflected power flowing toward the transmitter any more (none can be measured) that previous 50w cannot be traveling back towards the transmitter. Since it only has a choice of two directions, it must continue on toward the transmitter. In fact, since there are no reflections on the coax (none can be measured) ALL real power, incident to the Z0-match from either direction, is forced to head for the antenna. What other choice does it have?

Hey gang

I am not a paid promoter or anything, but I just bought a 4 element Arrow antenna for 6 meters. I am totally impressed by the workmanship and the ease of assembly...this antenna is a winner.

Antenna is far more durable than the brand name suggests...While I would not put it up at 100' feet on the Kansas prairie, the city dweller with a 40 ft tower gets an antenna that is a good value.

I bought mine for 100 bucks...new in box, but originally bought by WP4O. They are around 20 bucks more from Arrow.

I know that you can go pick tubing at the aluminum farm; I have done so many times and built many an antenna, but for those with a "time is money" situation, like me, or someone new to 6 meters and antenna building, what a nice deal the Arrow is.

I will take a few photos of the antenna, up close...to show the workmanship...and post 'em in the near future.

Do they allow phantom undetectable power waves flowing all over the place?
Methinks you have enhanced their work a mite.

Hugh is right, RTLT (round trip light time) for geo-stationary satellite is about 1/4 second, to the moon is about 2.5 seconds. Even earth bound there is some delay and can be easily measured. Best example of this is radar. Also, ever get echo in a local phone call? It does not require a satellite link to generate this effect. The phone company has suppressers for this, but sometimes they don't engage for some reason.

SGC doesn't put coax connectors on the output of their autotuners for
good reasons. Coax cannot stand the voltages involved in feeding an
8' whip on 75m. What you are planning will probably work OK on
20m-10m but I certainly wouldn't use coax between the tuner
and an 8' whip on the lower bands.

At a California shootout, I tested an SGC-230 with a 11.5' whip on
75m. Weather was misty and the base of the antenna arced over to the
grounded part of the antenna mount. Don't know why anyone would even
try an 8' whip on 75m since only about 1/4w makes it to the antenna
from a 100w transmitter. Talk about QRP!

Yea, that PT is pretty neat looking, but I was surprised how small they are when I finally saw one in person. Not as big as I was expecting from the ad's. Myself, I drive old beaters here, and have both ford and chevy. Have an old 68 ford f-250 that I've been kinda restoring. It has very little rust and was garage kept all it's 32 years. I drive it the most lately. Also have an old 81 chevy MC. I've been driving that thing for years and years it seems and I can attest to Tom's statements about the paint on GM cars. Fairly pathetic. The paint has peeled something awful on that car and looks terrible. But, the car still drives almost like new and has never left me stranded once. It's the car I take if I want a smooth highway trip. I do most the work myself. Thats why I can get away with old beaters. Half the parts on both vehicles are almost new. I keep thinking about springing for a new car, but I'm just too cheap. And I'm not one that needs a fancy car to feel stylish. A new car is one of the worst investments of money you can choose. I save 1000's every year from driving beaters. 100's a year just in insurance. Also I just like old cars anyway...I have a sickness for old trucks. I've had quite a few of those. I once had a new chevy Z-28 about 20 years ago. Real nice.. But it drove me crazy trying to keep people from dinging it up, etc. Seems like the first 2 weeks I had it I got 14 small door chips. Would drive me ballistic. My brother later totaled it when a dingbat slammed into him on the freeway... I don't have to worry as much with the beaters. MK

Cecil:

I snipped a bit out of your post, sorry.

How did you do? Well, I think the discussion went fine, not really a matter of how well either of us did. More important did we learn anything? My personal opinion - I think that you limit yourself by not looking beyond the steady state conditions. Most notably in the discussion of power. Power is a net scalar quantity determined from the addition of vectors. Power is the determined quantity, the addition occurs with the vectors.

Here is an example that will tie your use of the Smith Chart to my transient analysis and my discussion on the addition of power.

We have a 50 ohm line connected to a 300 ohm line. The 300 ohm line is 1 wavelength long. We measure a forward power of 100 watts in the 50 ohm line. We measure a forward power of 87.1795 watts in the 300 ohm line and a reflected power of 25.6410 watts in the 300 ohm line. What is the actual impedance terminating the 300 ohm line? I would like the answer in the form of R + jX. Use only your knowledge of voltage and power at the impedance junction. Hint, the answer lies in the addition of power in the 300 ohm line. Do not use the Smith Chart yet, please.

73,
Steve

Hi Peeps,

I'm having a bit of bother with NEC4WIN.
I'm trying to model a simple monopole antenna, and look at the
change in impedance with a wide range of frequencies.

I've created a 3 metre long groundplane antenna a zero height
above perfect earth. (I know this isn't accurate for real-life
situations, but I want to get a feel for what's happening..)
If I sweep the impedance over the range 4-40MHz I get pretty much the
expected results, *except* that the imaginary part of the
impedance never goes positive.
It sweeps up and down as expected, but always negative...

What am I doing wrong..?

Thanks...

>problems. (Someone more familiar with the intricacies of this problem
>may want to elaborate.)

I think this is a characteristic of TDMA systems in particular (GSM may also work like this). As I understand it each phone synchronizes to the cell tower it is using, and is assigned a time slot in which to transmit a frame. As the phone is moved further from the tower, the start of the transmission as viewed from the tower moves later and later into the timeslot. Eventually, at some distance, it will slip far enough that the tail of the transmitted frame ends up in the following timeslot and is interfered with by the phone using that timeslot. I don't know any details beyond this, but 15 miles does represent a 0.16 ms slip, which is larger than the 8 kHz timing that phones are often attached to, so that number sounds vaguely plausible.

I don't think CDMA (spread spectrum) systems have this problem, nor do older analog systems.

OK. I'm glad we agree it won't work this way with the real
transmitters we all use. I'd still like to understand the analysis you
are using.

>Keeping the discussion at the level where it
>has been is really an effort to address some fundamental concepts - IE. Does
>a total re-reflection of power really occur at the match point? What is the

>practical realities you mention come into play.

I think the actual concept is a total re-reflection of all "reflected
power" occurs at the match point. I'm not aware of any claim that
"power" was reflected.

>We have first assumed that the "relative" phase angle of the voltage
>arriving at the match point is 0 degrees. The phase angle of the reflection
>coefficient is 0 degrees because we have assumed that the ZO of each
>transmission line is purely resistive.

How can you do that? The line appears as a series of energy storage
and forwarding systems, an infinite number of series inductances and

shunt capacitances. Each of those components stores and releases
energy, and hopefully forwards it along the line to a load in our
application. Every transmission line has bandwidth considerations.

The line Zo isn't anything like the **characteristic impedance**
unless something is absorbing energy at the same rate as it is being
applied to the line, and the across (voltage) and through (current)
vectors are in the correct ratio at the load end of the line.

Now it's true an infinitely long perfect transmission line will behave
as a perfect resistance, but we aren't using a zero frequency source.
We are using an infinite frequency source, or at least you have
mentioned line wavelength or source frequency.

It is a line that just "is" what the impedance label says at all
frequencies.

Are you considering we are actually exciting the line with a pulse so
short that the line appears to be infinitely long, allowing us to
disregard the end termination and any reflections? (Or have I missed
something?)

If so, can you tell me how our generator will "see" the line as a
perfect "resistance" that is based entirely on the characteristic
impedance of the line? In other words, can you describe the mechanics
of how the line has a ratio of across (voltage) and through (current)
vectors that are not determiuned by what is connected to the far end
and the length of the line? Or does that come later?

>The total voltage at the match point is the vector sum of the incident and
>reflected voltage. The voltage transmitted through ("delivered to") any
>impedance junction is equal to this total voltage.

OK, I read up on that last night. I follow that concept, but my
textbooks all considered a steady state condition and I had to work
from the load back towards the source to find voltages and impedances
along the line. I couldn't start at the "middle" of the system.

I wrote:
>> That's why an open lossless transmission lossless line steps up

I beg to differ! With a lossless unterminated 1/4 wl line, if we could somehow feed power into that line, the voltage across the open end would be infinite.

The rub is the impedance at the generator would be zero ohms. We can't apply ANY power to the line because the across vector is zero. We have no voltage, and can have no power.

The reverse is true for a shorted lossless line. The end current would be infinite if we could some excite the infinite input impedance line.

Power reflection works well for understanding the above cases. Reflected power equal forward power. Net power flow into the line is zero watts in either case.

>Let's look at the short circuit using the way I handle the math with the

>1.41 - (1.41) = 2.82 a. Z = 0/2.82 = 0 ohms, the short circuit.

How I can measure 2.82 amperes into a short circuit with a voltage of zero volts? Can you describe a test setup that will allow me to prove 2.82 amperes will exist?

>+71.8 v in the 51.5 ohm line (100 watts) arrives at the 300 ohm line and
>sees an impedance discontinuity.

I don't understand how the 100 watts (I assume that is average power) at 51.5 ohms impedance arrives at the 300 ohm load, and why that load is 300 ohms. It seems as if we are looking at the system backwards.

When you define power, are you talking about RMS power, instantaneous power, or average power?

How do we make our generator source a given ratio of E/I without having a load impedance defined by the line's load? How can we define power as power flowing into a line when we don't define the line length or frequency of the source?

If I have a zero source-impedance transient source feeding a transmission line, what is the mechanisim that limits the source power to 100 watts and the ratio of E/I as ~50 ohms?

I can't get past this point, but when I do I'll go through the rest. Right now I vapor lock at the lines looking infinitely long and/or the transients being what we can consider infinitely short, and the actual applied power only being 100 watts but the reflected power being 400 watts in a system with only a single transient that is so fast the lines look infinitely long.

I can't understand why we would want to use a model that is so far from the operating condition that we can't even build a model, or

measure what we predict!

Unless I'm missing something. Can you tell me how to build a system like that, so I can measure the voltages and currents? Can we build an measure what you are describing? I know for a fact I can build and measure the system Cecil described, and the measuremenbts will agree with his analysis.

I'm not saying you are wrong, I'm just trying to understand why the reflected power concept is wrong...when I can build and measure exactly what that reflected power model predicts.

I'm trying to balance the advantages of using a model I can't build or measure against using a simple model that I can build and measure, and decide how the one I can't build can be verified to prove the one I can build and measure is wrong.

When I use models, I always like to use the most simple model that behaves like the system I'm emulating. Virtually all models have boundaries. We might find a theoretical case (that we can't actually build) that violates the boundaries but that doesn't make the model incorrect in real-world applications!

In all the arguing, bickering and feather preening that has gone on in this newsgroup, it's great to discuss a new concept in rational conversation. I appreciate your time Steve, and I'm sure many people are learning things from you in this exchange. No need to hurry with any answer, I have work to do until lunch tomorrow.

Is your RMS reading wattmeter reading average RMS power or peak RMS
power?

Even a PEP meter reads RMS power, it just reads the peak of the RMS
value.

Aside from that, I agree with you. If you have a true average reading
RMS meter...it stays put with 100% positive and negative symmetrical
modulation. So does the anode current meter.

However, a peak reading RMS meter will indicate a PEP value four times
the RMS average value while the current and voltage in the output
device appear stable.

Thanks. I finally got a chance to look at them. I'd never looked at the M12 .All I can say is why???? Those antennas look like too much work for me. All those twists and bends... Must be a construction and support nightmare.. I think I'll stick with fairly straight wires. Or as they say here, waaar's. MK

Perhaps we are talking about two different transmitter configurations.
Based on your original post, I assumed you were describing a high
level plate modulated transmitter whose unmodulated output power was
100 watts. When 100% modulated by a single sinusoid, the average
envelope power should increase to 150 watts.

On the other hand, maybe your wattmeter doesn't actually measure
average RF output power. I seriously doubt it measures RMS power
either. Most inline RF wattmeters square the rectified, weighted sum
of the instantaneous voltage and current, and display the result as
either forward or reverse power. The relative weighting of the
voltage and current are determined by the characteristic impedance of
the transmission line the instrument is calibrated for.

The average rectified voltage (current) of an AM transmitter output
will not change with the application of modulation. The envelope
voltage (or current) will vary sinusoidially between zero and twice
the unmodulated value resulting in an average value independent of
modulation, up to 100%. The RMS output voltage (or current) will
increase by 22.5% when modulation is applied however. Note that the
classical thermal type RF ammeter is responsive to RMS current while
a current transformer, followed by a rectifier and DC voltmeter
responds to average current. The thermal ammeter will show an increase
of 22.5% when modulation is applied but the averaging type will stay
unchanged.

>However, a peak reading RMS meter will indicate a PEP value four times the RMS average value while the current and voltage in the output device appear stable.<

Right--and thanks for that destinction. But, I still can find the extra 50 watts.

For a 100-watt AM signal, aren't we talking about a dynamic mixing process that yields output from 0 watts PEP to 400 watts PEP while exhibiting a true average output power of 100 watts?

Further, isn't the requirement for 50 watts of baseband audio only needed when the method of mixing involves the use of a modulation transformer in the process we call "high level" modulation?

Consequently, isn't a 100-W AM transmitter a 100-Watt AM transmitter regardless of how we make it happen?

Cecil, W6RCA wrote:
"Assuming a 1/2 WL 300 ohm line with a 51.5 ohm load, the returning reflected power will cause the originally existing reflected power at the 51.5 / 300 ohm impedance lump to cease to exist because of destructive interference."

I tend to think of some same-voltage batteries paralleled through a resistor. No current flows through the resistor because there is no difference of potential. Or, some oppositely polarized batteries adding to cause an increased current flow.

The reflected wave is nullified because it doesn`t appear on a 51.5 ohm coax connecting the transmitter with the 300 ohm line. It has ceased or it would re-enter the transmitter.

The transmitter sees 51.5 ohms thanks to the 1/2-wave impedance repeater (the 1/2-wave line). There is no impedance bump presented to the transmitter. The reflected wave can be thanked for eliminating the bump that the 300-ohm line would cause if it really looked like 300 ohms. It looks like 51.5 ohms.

The reflected voltage must add to the incident voltage at the 300 ohm line input to cause more current to flow into the line than would normally flow without the reflection.

I`ll speculate this happens due to 180 degrees between the transmitter and load, another 180 degrees in the reflection process, and a third 180 degrees between the load and transmitter. The odd number of phase reversals makes the incident and reflected waves additive across the input to the 300 ohm line. This increases the current into the line so that the voltage to current ratio in this case is in fact 51.5 ohms.

But we have two 1/4-wave line sections making up the 1/2-wave line. The 1/4-wave transformer impedance ratios apply and the voltage in the middle of the 1/2-wave section is high and the current is low. The 300-ohm line impedance is the intermediate between the high mid point impedance and the low 51.5-ohm impedance.

Best regards, Richard Harrison, KB5WZI

In the discussion, I simply assumed that the line had a characteristic
impedance that was real. The example as presented stated that ZO in one
line was 51.5 ohms and the ZO in the other line was 300 ohms. We also
assumed that each line was lossless. The concepts in the discussion would
not have changed had the ZO's been complex or the lines lossy.

More important are the concepts associated with wave travel. Here's an
interesting concept to think about. If the ZO of a line is complex, real
power can be delivered to a load having a reflection coefficient equal to 1.

>

There are no pulses. What I am considering is that when our perfect transmitter is instantly energized, it does not see the load, only the characteristic impedance of the line. The transmitter will have no knowledge of the load impedance until reflections from the load reach the line input. Once the reflections reach the line input, the effective line impedance (Vtotal/Itotal) changes but the physical characteristic impedance of the line does not (in theory). The transmitter will continue to drive a *forward* voltage, current and power consistent with ZO. The *total forward* voltage, current and power at the line input will change as a function of the re-reflections at the line input.

We can feed power into a lossless unterminated 1/4 WL line. We just can't deliver any *net* power to it. With a wattmeter, you would measure a forward and a reflected power, both being equal. As a result, there is forward voltage and current in the line as well as rearward voltage and current.

Why would the voltage be infinite? Let's assume we have this lossless 50 ohm 1/4 WL line with 100 watts forward and 100 reflected. The forward voltage would have a magnitude equal to 70.71 volts. Arriving at the open circuit, it sees a reflection coefficient of +1. The total voltage is therefore 70.71 + 70.71 = 141.42 v. The current would be 0 and the line impedance at that point is infinite.

> The rub is the impedance at the generator would be zero ohms. We can't
> apply ANY power to the line because the across vector is zero. We have

>

Again, there is a difference between forward power and delivered power. Although we are delivering no *net* power to the line, there is forward and reflected voltage and current in the line itself.

>
> The reverse is true for a shorted lossless line. The end current would
> be infinite if we could some excite the infinite input impedance line.

The end current would not be infinite. We are dealing with a combination of transmission line theory and circuit theory. See the comments below **

> Power reflection works well for understanding the above cases.

Correct - *net* power flow. Current and voltage are still traveling in the line.

>
> How I can measure 2.82 amperes into a short circuit with a voltage of
> zero volts? Can you describe a test setup that will allow me to prove

> 2.82 amperes will exist?

** We are dealing with the discontinuity between the end of the transmission line and the connected short circuit. The boundary conditions at this connection point are determined through the reflection coefficient. It is not a matter of determining current flow through the short circuit, rather we determine total current at the end of the transmission line. The reflection coefficient is equal to -1. The total current at the end of the transmission line is Iforward - Ireflected. Irefected = -Iforward.

In a measurement set up, you could measure forward and reflected power at the short circuit (in the line). You could also measure voltage at the end of the transmission line. In the case of the transmission line, we determine V and I from the boundary conditions. We then determine Z = V/I = 0. I think you may be having difficulty with this in thinking that I = V/Z, since Z = 0, I must = infinity. We define I at the end of the transmission line, not *in* the short itself, so we don't calculate I in this manner with a short circuit at the end of the line. Current *in* the short circuit is meaningless. We are determining I at the end of the line, through the defined boundary conditions.

> >+71.8 v in the 51.5 ohm line (100 watts) arrives at the 300 ohm line and

> at 51.5 ohms impedance arrives at the 300 ohm load, and why that load
> is 300 ohms. It seems as if we are looking at the system backwards.
>

A 300 ohm line is connected at the end of a 51.5 ohm line. When a forward traveling wave arrives at the end of the 51.5 ohm line it sees a 300 ohm impedance. When a rearward traveling wave in the 300 ohm line arrives at the 51.5 ohm line, it sees a 51.5 ohm impedance.

The issue is understanding the difference between a physical impedance discontinuity and line impedance. The physical impedance discontinuity at the junction never changes. The line impedance changes only as a function of changing Vtotal and Itotal at the junction. Line impedance is never a mechanism for wave transmission or wave reflection.

>
> When you define power, are you talking about RMS power, instantaneous
> power, or average power?
>

I define power as P = |V| |I| Cos(T), where |V| and the |I| are RMS values and the T is the phase angle difference between V and I. This is fine as long as I am consistent in relating V, I and P.

> How do we make our generator source a given ratio of E/I without
> having a load impedance defined by the line's load? How can we define
> power as power flowing into a line when we don't define the line
> length or frequency of the source?

>

The initial forward power delivered to the line is a function of ZO, not the load impedance. When reflections from the load arrive back at the source, re-reflections are created as a function of the source's output impedance. These re-reflections add to the initial forward power.

What we predict from the model are the steady state conditions. These are what we measure. There is no disagreement in this discussion as to the steady state power levels anywhere in the system.

To understand this, we need to run through a transient analysis in detail. The model of reflected power predicts the steady state conditions based on already knowing the steady state conditions. If you know the answer, it's easy to come up with numerous ways to explain it. We need an answer that is consistent with all aspects of transmission line theory and circuit theory.

Here's an important first point to consider. In all transmission line systems,
matched or mismatched, the power delivered to the transmission line is always equal to Pforward - Preflected at the transmission line input. The total reflection model was developed based on assuming that Pforward = Pdelivered + Pre-reflected, where Pre-reflected is the total re-reflection of Preflected. This would mean that in all transmission lines
systems, a total re-reflection of power is always occurring at the transmission line input.

Source record: 178454

I've seen the term "RMS power" show up a couple of times on this thread, so it's time to repeat some comments about this.

RMS is a mathematical calculation which finds a use in relating the heating effect (or ability to do work) of power to a voltage or current. As it turns out, the AVERAGE power = Vrms^2 / R or Irms^2 * R. It's because of the relationship between the RMS values of voltage and current and the AVERAGE power that they're widely used. An RMS value can be calculated for any periodic waveform, including a power waveform, but the RMS value of a power waveform has no everyday practical use. The heating effect, or ability to do work, is equal to the AVERAGE, not RMS, value of a power waveform. RMS and average are different for most waveforms. They are of course the same if the power doesn't change with time, but this is an exception. If the power varies with time, and you want to know the overall effect it will have, calculate and use the AVERAGE value, not the RMS.

I sometimes see "RMS power" used with respect to audio amplifiers. As far as I can tell, this is due to ignorance, or perhaps it has some marketing advantage. But I know of no real use for this value in everyday electrical or electronic calculations.

Rick, K1BQT wrote:
"---my RMS wattmeter stays glued at 100 watts output."

That`s a possible problem. My wattmeter reads average watts. My voltmeter and ammeter read r.m.s. values.

Unless you have a very selective wattmeter which is capable of separating the carrier from its sidebands, the a-m carrier and sidebands increase the total input to your meter with modulation.

The carrier`s average power is unchanged with linear amplitude modulation. But, the total of the carrier and its sidebands rises by 50% from the unmodulated carrier total power output. This is the steady state 100% modulated average power output of the transmitter.

That modulator power has no other load than the final amplifier in the ordinary plate modulated stage. The audio power is not dissipated in the transmitter but is mixed with the r-f in the final stage. It exits the transmitter as the product of mixing (the sum and difference frequencies) which is r-f generated in the final amplifier, along with the carrier itself.

Mark,

I know the feeling exactly. And I don't worry so much about putting holes in the old ones for antennas. My wife (ex) used to say when I'd come home with a new car, "WELL, I guess you're gonna poke holes in this one, too, for them dumb radios". LOL!! Ever heard that from an XYL before? I betcha most of the hams in here can relate to that!

I used to think I had to have a new car every other year or so, but time "heals" all wounds (pocketbook) I never thought I'd keep that "new" 1987 Celebrity for 13 years, either. But it still runs just as well as a new one, it's long since paid for, and if I want to stick another antenna on it, it doesn't exactly hurt anything.

My ex-Mother-in-law bought a 1980 Monte Carlo in '80, and just recently sold it after voluntarily surrendering her drivers license. She realized that at age 86, she just wasn't as sharp as in her younger days. The Monte still looked as new, no rust, and, with a good wax job, would look great. It still drove as new, smoothe and quiet, with---get this- 37,000 ACTUAL miles. The interior was like new. I should have bought it myself, but can't justify 3 cars. I ain't getting rid of my Z34.

BTW, have you ever seen people that put antennas on their cars for no reason? One or two radios and 6 antennas all over the trunk? I know someone like that! Going down the road, his Aurora looks like a moving field of sawgrass!! I can remember the days when a ham might have 4 or 5 separate radios in the mobile. But now, with the multi-band rigs and antennas, one can get by with no more than 3. I have 2: HF and 2M/440. I think it is so silly to "decorate" one's car with antennas when 1 or 2 will do. LOL!

"Consequently, isn`t a 100-W AM transmitter a 100-watt AM transmitter no matter how we make it happen?"

Yes. But, when an unmodulated low-level, high-level, out-phased modulated, or whatever a-m transmitter is on the air its rated output is being transmitted (hopefully). When modulated, that same carrier signal is still there (and unphased by the modulation?). Symmetrical sidebands appear on either side (both sides) of the unchanged carrier signal. Their power is an addition to the unmodulated carrier power.

I found out the answer to this usage of RMS power. The audio folks have co-opted the RMS idea to mean the following: If the signal is a single sine wave, then RMS power is understood to mean the average power output due to that sine wave. It is deceptive to the following extent: An amplifier with a certain "RMS power rating" may go completely flat on peaks that are only a little greater than the RMS rating. Anyway, the use of the term is pervasive.

Okay, we're making progress. I have bids of 0%, 22-1/2%, nearly 50%, and 50% for anticipated average power increases on voice peaks--depending on how you meter it or interpret it. The ARRL Handbook says to expect a 50% increase. Shouldn't this be a cut-and-dried issue after 75 years?

Silicon bronze is commonly used in the boat building industry,
especially for wooden boats. Check with a marine supply company.

> transmission line input.

This is a misleading statement. The total reflection model was based on
assuming there is no measurable reflected energy reaching the transmitter,
i.e. based on the existence of a Z0-match somewhere in the system beyond
which point no detectable reflections exist. The Conservation of Energy
principle then comes into play. If there are no reflections seen by the
transmitter, all of its power is delivered into the system. There is
simply no place for reflected energy to go except back to the load so
it is no stretch of the imagination to declare that all reflected energy
has been re-reflected.

In a system containing a Z0-match, the reflected energy simply has no
"choice" of which way to go. It cannot go toward the generator, it cannot
stand still, and there's only one other place left. Call it anything
you want, the energy in the reflected wave is sent packing back toward
the load by the Z0-match.

There is absolutely nothing in the steady state model that prohibits
reflected energy from reaching the generator. In that case, there is
obviously NOT total re-reflection. Total re-reflection, in that case,
is a convention, not a scientific fact. I doubt that anyone knows
exactly what happens inside a generator that has reflected energy
flowing backwards through the tank circuit to/through the source.

It should be Rick, but few hams of today know little about the technique(s) behind the subject. I think it falls into that new category of ham radio called outmoded, outdated, irrelevant or some such term. Most of the new hams don't fool with anything that does not suit their immediate need. They declare it useless unless it fits exactly what they want. I would venture a guess that most of them do not even have a technical handbook to which they could refer.

You have received some answers about the delay time due to the radio waves. There can also be some delay in the way the signal is processed. I am not up on the relay system for the telephone circuits, but it is a factor to add in. Also it may not be a simple repeat, but the signal could travel over some ground stations, back to a sat and back down again or it could pass from several sats then to the ground.

I certainly looked at the transient conditions. I have Walter C. Johnson's book copyright 1950. That's why I am sure that reflections on the coax are snuffed out at the Z0-match point immediately upon their appearence during steady state. Canceling the reflections leaves the reflected energy with nowhere to go except back toward the load. You can call that re-reflection or a virtual short or gibbildysquatch, but the reflected energy does indeed change direction at the Z0-match point and conservation of energy is the only reason we need.

> Power is a net scalar quantity determined from the addition of vectors.
> Power is the determined quantity, the addition occurs with the vectors.

I think I remember you calculating the power before adding the coherent scalars in those phantom reflected waves on the coax. IMO, that's a mistake. Power is a scalar value resulting after the vector addition of the coherent phasor values and is simply energy measured while passing a point. There's no reflected energy passing any point on the coax.

> Do not use the Smith Chart yet, please.

How about the equations that generate the Smith Chart? :-) I'll take a look at your puzzle after choir practice.

To my knowledge, two patents have been issued, the one being discussed (6,104,349), and just within the last couple of days, number 6,127,977, for an implementation of a fractal microstrip (patch) antenna. Saying a patent is for a type of antenna is almost always misleading. A patent covers only, and exactly, what is described in the claims (and modifications which are "obvious to one skilled in the art", as interpreted by a court as necessary). To see what a patent is for, you have to read the claims. You can look at these and other U.S. patents at http://www.uspto.gov.

Perry,
You can do that, but use a coax with the highest voltage
rating you can find. Depending on frequency of use, you may
not be 'happy' with the performance of the 8' whip. That
whip on the lower HF bands leaves a ~lot~ to be desired.

Who cares? YOU are the one who sold it for $200. He's only asking $250 which is about $150 off the price of a new one. Seems to me it's your mistake, not his. I'm not sorry you lost money, but you shouldn't be jealous because he is making a buck. He probably had a shipping fee to come out of that extra $50, had to advertise it, answer emails (and he did) and will have to package it for resale. He's not getting rich off your mistake, maybe getting a few bucks for his troubles. SMILE. Things could be a LOT worse. :-)

Matt,
As stated above I don't see an advantage to shortening either a vertical 1/4 wave GP or a 1/2 wave dipole for 10 and/or 15M. Full size just isn't that large!
But, I have used helically wound 10M ants for mobile and potable operations very successfully! I have played with wrapping my own on an old fishing pole but that can be tedious and tuff to tune / stabilize the wraps. It is much easier to buy an 11M (CB) helical mobile antenna (cheap at a flea market!) and remove coils from the top load (most are top loaded) until it tunes for 10M. Be sure and buy an antenna that is plastic covered. Some use a resin which is very difficult to remove. The plastic coatings are soft and flexible. Be sure and seal the top when done either with the original cap and some silicone or some epoxy glue.
No reason why this wouldn't work for a GP antenna's radiator.... or even as a rotatable dipole if you used two of them!
Hope this helps.

Have to agree with all the comments on the antenna being mounted on the trailer hitch. Get some 1/8" aluminum and make urself a bracket that you can mount above the taillites. I've used hamsticks there on 40-10M with great success. ABOVE ALL, make sure you have a good ground to the sheet metal of the body (qwhich may also be ur problem using the trailer hitch)
As for the RFI, I can't help. Had a 94 Cherokee 4.0L and never had a bit of RFI on any freq. Suggest trying the ususal plugs/ wires route 1st, then hitting tthe handbook for more suggestions

I snipped a bit out Cecil and really just want to address some of the basics
at this point.

In your previous post you did say the following: "It remains 71v as it
flows unmolested through the virtual 50 ohms at the Z0-match."

The 71 v does not travel or flow through the ZO match into the 300 ohm line
as a forward voltage of 71 v. A forward voltage of 71 v in a 300 ohm line
is equivalent to 16.8 watts of forward power, so we know this is not the
case. The forward voltage of 71 v *always* sees the 300 ohm impedance
discontinuity. This is the basis of all transmission line theory from which
the steady state conditions can be determined.

The fact of the matter is that the forward 71 v traveling in the 51.5 ohm
line never really "sees" the ZO match at the match point. A forward or
rearward traveling wave only sees the characteristic impedance of the
transmission line in which they travel and they "see" any physical impedance
discontinuity in that transmission line. The 51.5 ohm impedance at the
match point is the steady state "line impedance". Line impedance is never a
mechanism for wave transmission nor is it a mechanism for wave reflection.
The line impedance in the center of the 300 ohm line is 1748 ohms, but this
does not impede forward or rearward wave travel in any way.

As you correctly state above, line impedance is simply the ratio of total
voltage to total current at the match point. It is no more complex than
that. At all times, Vforward/Iforward = ZO and Vrearward/Irearward = ZO.
The total voltage at any single point is Vforward + Vrearward. The total

current is Iforward - Irearward (this depends on the convention used for current. In some conventions, Itotal = Iforward + Irearward, in which case, Irearward = - Vrearward / ZO)

How is this total voltage (line impedance) determined at the match point in our example?

The forward voltage at the match point from the 51.5 ohm line is +71 v. The reflected voltage at the match point is +50.2 v. The rearward voltage from the 300 ohm line is -173.2 v and the re-reflected voltage is +122.5 v. The total steady state voltage at the match point is 71 + 50.2 -173.2 + 122.5 = +71 v (some rounding errors). Line impedance is a steady state result of how the forward and rearward voltages interact at the match point, it is *never* the cause of wave reflection or transmission. The only mechanism for wave reflection is the physical impedance discontinuity at the junction.

Understanding these concepts requires a lot more analysis than looking at a Smith Chart or looking at only the steady state power levels.

As for 100 w + 100 w = 200 watts, power is a scalar quantity but the voltages and currents that combine to create the total power are not. They are complex quantities having magnitude and phase. Let's assume for the moment that the forward source power in the 300 ohm line is 100 w and that the re-reflected power is 100 watts. Let's designate one power P1 having a voltage V1 and a current I1. Let's designate the other P2 having a voltage V2 and a current I2. If Zo is a pure resistance (cos(theta) = 1) we know the following:

P1 = |V1| * |I1| and P2 = |V2| * |I2|

Since both powers are in the same 300 ohm line we know the following is true at all times: |V1| = |V2| and |I1| = |I2|. We can also determine that |V1| = |V2| = 173.2 v and |I1| = |I2| = 0.577 (ignoring rounding errors)

Now what happens when these two signals add together. In all cases, the total voltage is equal to V1 + V2 and the total current is equal to I1 + I2. What happens if V1 and V2 are not in phase?

What if V1 = 173.2 v @ 45 degrees (P1 = 100 watts) and V2 = 173.2 @ 20 degrees(P2 = 100 watts)?

The total forward voltage will be equal to 338.2 @ 32.51 degrees and the total forward power will be equal to 381 watts. If V1 and V2 are in phase, the total forward power will be 400 watts. If V1 and V2 are 90 degrees out of phase the total forward power will be 200 watts. If V1 and V2 are 180 degrees out of phase, the total forward power would be 0 watts (in which case 100 w + 100 w = 0 w).

As this relates to our example, the actual forward source power in the 300 ohm line is 50 watts and the forward re-reflected power is also 50 watts. When these two powers add in phase, the total forward power is 200 watts.

Since we disagree at such a fundamental level re: basic transmission line theory, I thank you for the discussion and will end it here.

73,
Steve

Tom:

Your points are well spoken and correct. The practical matters associated with this discussion are another matter entirely and will overshadow most of the concepts discussed here. Keeping the discussion at the level where it has been is really an effort to address some fundamental concepts - IE. Does a total re-reflection of power really occur at the match point? What is the mechanism creating the steady state impedance match? etc. From there, the

practical realities you mention come into play.

> transmitter we would use?
>

We have first assumed that the "relative" phase angle of the voltage
arriving at the match point is 0 degrees. The phase angle of the reflection
coefficient is 0 degrees because we have assumed that the ZO of each
transmission line is purely resistive.

> Now here's what I don't quite remember. Does the reflected voltage add

> increases while the current decreases.
>

The total voltage at the match point is the vector sum of the incident and
reflected voltage. The voltage transmitted through ("delivered to") any
impedance junction is equal to this total voltage.

Current is handled in a similar manner but there have been several
mathematical conventions used to handle it. Some people like to use the
convention that reflected current is equal to incident current time a
negative reflection coefficient, others like to use incident current times a
positive reflection coefficient. Both can be considered correct, so long as
the math is consistent throughout the analysis. In my case, I prefer to use
a positive reflection coefficient and then determine total current at any
point on the line to be Iforward - Ireflected.

> That's why an open lossless transmission lossless line steps up

> and infinite current...if we could somehow feed power into a line with
> voltage and current 90 degrees out-of-phase.
>
> I'm lost at this point. How do we double the voltage without reducing
> the current?
>

At an open circuit load, the current will be zero but the voltage will not be infinity, Z = V/0 = infinity. At a short circuit load, the voltage will be zero bit the current will not be infinity, Z = 0/I = 0.

Let's look at the short circuit using the way I handle the math with the current. A forward power of 100 watts arrives at this short circuit from a 50 ohm line. The incident voltage is 70.711 v. The incident current is 1.41 a. Since the reflection coefficient is -1, the reflected voltage is -70.711 v and the reflected current is -1.41 a. At the short circuit, the total voltage is +70.711 + (-70.711) = 0 volts. The total current is 1.41 - (1.41) = 2.82 a. Z = 0/2.82 = 0 ohms, the short circuit.

The issue of adding two forward voltages and currents is different because both waves are traveling in the same direction. In our specific example we are talking about adding a forward source wave to a forward re-reflected wave. In this case, Vtotal = V1 + V2 and Itotal = I1 + I2. Since both V1, I1 and V2, I2 are traveling in the same impedance, when V1 is in phase with V2, I1 will be in phase with I2. If V1 and V2 are in phase, the total forward voltage will double and the total forward current will double causing the total V*I product to increase by a factor of 4. If V1 and V2 are 180 degrees our of phase, the total forward power will be 0.

> >The rest has been explained in several of my previous posts.
>
> I haven't had time to follow all the posts until now, and I know your
> not going to be like someone else would be and tell me to go back and
> read them all! I need to understand the stuff above before going on!
>

Yes, I will be happy to continue the discussion in this post. I will restate it here:

+71.8 v in the 51.5 ohm line (100 watts) arrives at the 300 ohm line and sees an impedance discontinuity. As a result, a voltage reflection occurs. The reflection coefficient is +0.707. The reflected voltage is equal to +50.7 volts (50 watts reflected in the 51.5 ohm line). The total voltage transmitted into the 300 ohm line is equal to +122.5 volts (71.8 + 50.7). This is 50 watts of forward power in the 300 ohm line.

Continuing, we know that the steady state reflected voltage arriving at the impedance
junction is equal to -173.2 volts (100 watts in a 300 ohm line). It too sees the impedance discontinuity. The reflection coefficient in this direction is -0.707. The re-reflected voltage at the junction is +122.5 volts (50 watts in a 300 ohm line). As a result, the total forward voltage in the 300 ohm line is 245 volts, which is the total 200 watts of *total* steady state forward power. The rearward voltage transmitted back into the 51.5 ohm line is equal to -50.7 volts (50 watts ina a 51.5 ohm line). This rearward voltage adds to the original reflected voltage (+50.7 volts) and the two cancel to a net *total* rearward voltage of 0 volts. Hence, no rearward traveling wave past the match point - the steady state match.

The impedance discontinuity between the 51.5 and 300 ohm lines never changes. The effective steady state line or input impedance at that point is 51.5 ohms only because the rearward voltages cancel each other leaving a total voltage at that point equal to 71.8 volts:

Total voltage at match point = (forward V in 51.5 ohm line + reflected V in 51.5 ohm line) + (reflected V in 300 ohm line + re-reflected V in 300 ohm line) = (71.8 + 50.7) + (-173.2 + 122.5) = 71.8 v

>
>
> I'm just trying to get a handle on what the fuss is all about.
>
>
> 73 Tom

From my perspective, the issue goes back to understanding the fundamental concepts - is it correct to state that a total re-reflection of power is occurring at the match point, thereby claiming that the impedance discontinuity at the junction (or match) is not the mechanism for wave re-reflection. This being incorrect, why not just explain the process in a manner consistent with theory?

Steve

403. 2mtr mobile antenna on house..

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-04 00:00:00 UTC
From: andy@equinox22.f9.co.uk
Message-ID: <xHGC5.28736$CI1.626238@stones>
Source record: 178500

Having recently moved to this house i've had little chance to work out what my neighbours feelings are towards aerials. I have a 2x5/8 2mtrs (white fiberglass) base aerial in the garage that i could bolt to the back of the (terraced) house, i wonder if it's possible to use a mobile aerial on a small bracket for the time being. I'm on fairly high ground and have so far been getting quite good results with just a hand-held with it's little 'rubber duck' aerial.

I've noticed that you can get some very nice looking stainless steel 2x5/8 aerials which ,i hope, would have a very low visual impact. I hav'nt managed to find my radio catalogues yet (i think i packed them !) but i seem to remember reading that some of these areials will work with out a ground-plane. Yes,i realise that normally the car acts as the ground but i'm curious to know whether i really have read about these aerials ..

Any ideas ?

Regards

Rick, K1BQT wrote:
"---shouldn`t my wattmeter read 150 watts (100 watt transmitter, 50 watts modulator power) at 100% modulation?'

Exactly.

My experience is the current in the common-point r-f ammeter in an a-m broadcast station rises by 22.5% at 100% modulation. 1.225 squared (power is current squared times the common-point resistance) is 1.5, which indicates exactly 50% increase in power output.

I carry a Z34 around for ballast in the back of my SD F250 with the
turbo diesel.

Unfortunately, the turbo diesel has noise exactly like ignition noise.

It comes from the injectors, which have a 1000 volt pulse generated
when the voltage is removed to close the injector!

Mechanically, I've never had a problem and have driven Ford trucks
since 1980. I quit buying GM in 78, after getting screwed on a new
Monte Carlo V-8 with a 4 cylinder transmission and factory installed
rust under the paint. That car had a cam lobe go flat in 1980, at
52000 miles. Since it had holes in the body (the friggin ROOF none the
less), I got rid of it..

Whoa! I have stayed out of this because it was more a matter of semantics than anything else. But! a 100% modulated AM Transmitter 100 Watt Carrier Power would show 50 watts in the carrier and 25 watts in each sideband (average power) still adding to 100 watts. What am I missing?

The real advantage of SSB was the eliminating first the carrier (now 50 watts each sideband) for a 3dB gain. Next the elimination of the unneeded sideband (100 watts in the single sideband) for an additional 3dB. A total of 6dB, and a total system gain of 9db when taking a receiver/transmitter in account.

VE9SRB wrote:
> The impedance discontinuity between the 51.5 and 300 ohm lines never
> changes.

If that were true, the Smith Chart and stubs would not work. Obviously the *physical* impedance discontinuity never changes but the apparent discontinuity disappears because of the reflections which effect a Z0-match and provide a virtual 51.5 ohm load at the Z0-match point. The physical discontinuity is the foundation for the virtual impedance achieved at steady state just as the physical discontinuity at the end of a stub is the foundation for whatever virtual impedance we may achieve at the other end. If the impedance looking into a Z0-match never changes then the impedance looking into a shorted 1/4WL stub never changes. What is the impedance looking into a shorted 1/4WL stub?

> re-reflection. This being incorrect, why not just explain the process in a
> manner consistent with theory?

Sounds like you're begging the question and setting up a straw man. Nobody says the impedance discontinuity is not the mechanism for wave re-reflection. Without the impedance discontinuity, a Z0-match could not exist. The steady-state model simply drops out all the transient model parameters that cancel or wind up with a zero value and it treats all powers as scalars.

The issue, from my perspective, is: Does the steady-state model continue to be a good enough tool for most everything we do, including stubs and Smith Charts? Since there is no argument about steady-state conditions (except maybe for phantom waves which can't be measured and have no effect) why is a more complicated model needed? If a more complicated model is needed, why not drag out the entire set of quantum physics equations?

Tom, W8JI wroyte:
"I assume the angle of reflection is zero degrees so you are just able to ignore it?"

A reflection requires a reversal of current or voltage, but not both. The phase angle is thus 180 degrees. The reflected voltage adds to the incident voltage at a high impedance discontinuity. The reflected current adds to the incident current at a low impedance discontinuity.

Neither voltage nor current rise to infinity at an open or short circuit. They double. The E & H fields contain equal amounts of energy. Kill one, and its energy must be transferred to the other to save the energy.

Tom wrote: "I`m just trying to get a handle on what all the fuss is about."

Me too.

For sure, you have a transmission line and system between a transmitter and load, and if that system has negligible loss, the power delivered to the load is the same as that from the transmitter. The voltage to current ratio at any point is the impedance at that point. But, the power at any point is the same. There are forward and, with reflections, there are reverse powers. These oppositely traveling powers can be separated using a directional coupler because the voltage and current are placed in phase opposition by the first reflection of the incident wave. It is easy to take current and voltage samples and adjust their magnitudes to be equal. If they are out of phase the samples cancel. If they are in phase they double the magnitude of either voltage or current sample alone. Thus we have the Bird wattmeter.

The Bird will show that in a matched line there is no reflected power in the matched section of line while the matching line section may have any required amount of reflected power.

Best regards, Richard Harrison, KB5WZI

Bill:

Just wanted to comment, good summary.

The work of Johnson, Slater, Kraus and others predate our discussions over the past few years and there work is not in dispute. In all of these works, they clearly describe the wave reflections as a function of load impedance for the forward wave and "output" impedance for the rearward arriving back at the source. In the case of an impedance junction, as in the 1/4 wl transformer, they clearly describe the wave reflections and re-reflections as a function of the ZO discontinuity at the junction. In no case do any of these works state or imply that a total re-reflection of power is occurring at a match point as a result of an impedance match. This concept was independently developed, presented and then became widely accepted as it was an easy concept to understand (correct or not). My discussions are not original nor are they new, they have only been presented to challenge the widely accepted concept that a total re-reflection of power occurs in impedance matching.

On one other point, you made the following statement: "At the generator there is an adjustment of the voltage and current that the generator sends to the line." Many people read this statement and believe it to mean that the generator is "actively" adjusting its output levels as if in a direct response to the reflected energy arriving back at the generator output from the mismatched load. In my opinion (this may be a matter of semantics) the generator is not actively adjusting it forward driving output at all, rather the "net" output from the generator is changing. The net output from the generator is a function of the generator's forward driving output (a function of ZO) and the re-reflected forward energy created at the generator output. The internal voltage and current within the generator are changing only as a function of the level of rearward reflected energy delivered back into the generator. In the steady state, the internal stages of the generator see two "sources". One is the internal forward driving source within the generator and the other is the external rearward driving source created at the generator output as a result of wave reflections. This can be appreciated by comparing the internal power dissipation occurring within a transmitter when it operates into a match load or a mismatched load. A transmitter delivering X watts of power to a matched load may have more internal power dissipation occurring than when it delivers X watts of power (Pf - Pr) to a mismatched load (in this case load R > Zo).

> case.

The voltage doesn't know it's in a 300 ohm line. The reflections have caused a virtual impedance of 51.5 ohms. The measured voltage on each side of of a Z0-match is almost the same and the Smith Chart tells us why. Consider the Z0-match as a smooth on ramp to an SWR circle.

> The forward voltage of 71 v *always* sees the 300 ohm impedance
> discontinuity. This is the basis of all transmission line theory from which
> the steady state conditions can be determined.

But once steady state conditions have been achieved, all the zero terms and the terms which cancel can be dropped from the equation. Simplifying the equation requires introduction of the virtual impedance concept, upon which the Smith Chart is based. Take away the virtual impedance concept and you have to throw away the Smith Chart.

> The fact of the matter is that the forward 71 v traveling in the 51.5 ohm
> line never really "sees" the ZO match at the match point.

Of course it sees the virtual impedance at the Z0-match point. Otherwise there would be reflections on the coax. Consider the following:

100w --->---51.5 ohm coax---x---1/2WL 300 ohm twinlead----300 ohm load

100w --->---51.5 ohm coax---x---1/2WL 300 ohm twinlead----51.5 ohm load

There are reflections on the coax in example one. There are no reflections on the coax in example two. The physical impedance bumps are identical but the virtual impedances are not.

> Understanding these concepts requires a lot more analysis than looking at a
> Smith Chart or looking at only the steady state power levels.

The concepts are easy to understand. The question is whether they are needed or not. After all, those concepts are just a math model that exists in human minds and may or may not bear any resemblence to reality. Why is a more complicated model necessary and if it is necessary, why not make it even more complicated? You are chosing to omit a lot of the quantum physics equations for your model. Why?

> Since both powers are in the same 300 ohm line ...

But they are not in the same 300 ohm line. One is in a 51.5 ohm line and
one is in a 300 ohm line and those powers must combine or be dissipated.
Those powers are ***SCALAR*** values.

> Now what happens when these two signals add together.

Vg + V- = V+ and Ig - I- = I+ Vg*Ig=100w, V-*I- = 100w, V+*I+ = 200w

The phasors add vectorially, the scalars add non-vectorially.

> As this relates to our example, the actual forward source power in the 300
> ohm line is 50 watts and the forward re-reflected power is also 50 watts.

Measurements prove otherwise. There are no reflections on the coax. Therefore
all the generated power enters the Z0-match.

> When these two powers add in phase, the total forward power is 200 watts.

Powers are ***SCALAR*** values. It is impossible to add them "in phase".
Voltages add in phase. Currents add in phase. Powers do not add in phase.

> Since we disagree at such a fundamental level re: basic transmission line
> theory, I thank you for the discussion and will end it here.

We do not disagree on basic transmission line theory, Steve. I have taken
a devil's advocate position and tried to defend the steady state math model.
All math models are flawed. My entire purpose was to ascertain exactly how
well the traditional steady state model, including the Smith Chart and stub
design, could be defended. How did I do?

What Heaviside did was to recast Maxwell's original equations into
the simpler form made possible by vector calculus, which both
he and Gibbs were championing at the time. He and Hertz
worked on this problem, and the equations they came up with
were originally called the Heaviside-Hertz equations. Time
and textbook writers have transmogrified that into the familiar
"Maxwell's equations."

100 Watt Carrier Power would show 50 watts in the carrier... ???
Sounds like the fuzzy math I heard a guy talk about on the radio last
night :-)

As I understood the original post, the system being discussed was a
plate modulated transmitter. The steady state carrier power without
modulation was 100 watts. Introduction of the modulation, through the
modulation transformer has the effect of doubling the plate voltage
during positive audio peaks. During negative audio peaks, the plate
voltage is essentially zero. The instantaneous power during positive
modulation peaks is four times the unmodulated carrier power or 400
watts. At negative modulation peaks, the RF output is zero. The output
power averaged over an entire sinusoidal modulation cycle can be shown
to be 150 watts, 100 watts in the carrier and 25 in each of the
sidebands.

The derivation can be found in nearly any textbook on radio
engineering. If you are interested and can't find it, let me know and
I'll post it.

Tom,

You couldn't have a Z34 in your Ford truck! You'd never be able to
CATCH one! LOL. And even the Lightning series wouldn't be able to
catch one on a crooked road--it'd turn over while the Z34 took the
S turns with ease. LOL!

Everybody's experiences are different. Mine just happened to be bad
with FoMoCo. I didn't like being Found On Road Dead! LOL!

Currently, I am having a hard time ignoring the Chrysler PT Cruiser!
Turns my head every time.

Best 73 to ya,

Jerry

Easy. You quoted that physics text before. I paid attention because it was the same as I had used in one of my physics courses. But mine had to be the first edition because my use predates the copyright of the second edition.

Ah, The Dictionary again :-) What I had in mind is *any* flow of current is evidence of power being consumed, or dissipated, if you prefer. Even a radiating antenna in the most remote corner of space is doing "work" by sending out RF energy. I know, the energy doesn't actually do "work" until it is dissipated into a load somewhere, if it ever is...but still, the "work" has been done, if not other than in the transmission of the RF.
Looks like you're trying to say that power moves even if it doesn't do any work. I thought The Dictionary ruled that out.

Phil,

That well could be, however, what started out as a *simple* low or no cost item was changed greatly by all the politicians involved... There is no good reason -except pork barreling- that something so simple had to be made SO complex and * very* costly... While I sure there are many who would disagree with me I feel the veto justified.

Dear Tom, Steve, et al,

If you are unable to sort out your problems on imaginary ideal lines with purely resistive Zo and terminations, how on on earth are you going to manage in the real world with real lines and complex Zo and terminations.

Did you know that reflection coefficients on real lines can approach 2.4 ? How would you manage your calculations in such cases. Smith Charts ? - don't make me laugh !

Hint: reflections and echos are much better analysed as functions of time rather than of frequency and wavelength. Think in terms of transient response to sudden shocks. What happens following t = 0 when the morse key is depressed. ?

Go back well before Kraus, Terman, Everitt, et al, to Oliver Heaviside who had it all worked out 110 years back and then to Carson.

Incidentally, the mathematical description of the mechanics of radiation and e.m. fields presented in modern text books, frequently quoted by ambitious newsgroup guru's and attributed by habit to Clerk Maxwell, is in fact entirely due to the work of Heaviside. Heaviside translated the ideas of Maxwell into the form we (or some of us) are familiar with. Let's give credit where credit is due.

I knew I would get a rise out of you Chevy lovers. I had a 92 Z34
also. Actually I have had 2 92 Z34's. The first one only lasted 2
weeks because of a screwed up neighbor kid who decided that it looked
better burnt to a crisp. Almost burned the house down too because it
was in the garage when the little dirt bag set it a blaze. Went down
with check in hand and got another. Wish I still had it but houses
come before pleasure.

I've used an MFJ 989C for some time, but I still prefer the old MT3000 "I
used to have" for ease of tuning.
Now you have me thinking of checking out e-bay again even though large
auctions usually result in the bidder paying quite a bit more than the verge
used price.

The usual smug, supercilious crap from Reg.

We know about Heaviside and what he did, and the usual textbook
Maxwell's equations are what work for us ordinary ignoramuses.

Waal,

It's all in what you get used to. The Z34 is quite a cream puff be-
cause I refuse to take it out in the rain even--unless I get caught
out. It is just fun to drive. On trips, it is very comfortable and
gets right at 30 MPG--even with the 3.4L engine. People think because
it's a 6 cyl, that it won't really get up and go, but it will. I just
don't do that, but it's nice to know that I CAN, and it is handy in
tight passing maneuvers.

All joking aside, I don't know what it is about Fords and ignition
noise. It seem to always have been that way. When we used to run
AM rigs back in the '60s we could tell there was a Ford passing by
because of the pulse noise in the receiver--increasing in pitch and
speed as the driver shifted gears, slowing down when he pressed the
clutch. Look out the window, VOILA, there'd be a Ford going by. LOL!
It still happens to my 706 in the car. Some Fords make no noise, others
completely blank out the receiver.

If you are having trouble with noise, I wish you the best of luck in
curing it. Glad we can razz each other and have a little fun.

Message-ID: <20001004021851.16567.00000196@ng-cr1.aol.com>
Source record: 178480

The answer to your delay questions is rather simple math. Radio signals travel at the speed of light, ie 286,000 miles per second. If the distance to the repeater is aproximately 22,000 miles, add 22,000 miles for the return (44,000) total, and divide by 286,000. The path delay is 153 milli-seconds, or 0.153 seconds. If the repeater does some type of signal/voice processing/error correction that time should be added to the path time.

Hope this helps, regards, Hugh KF6HHS

Roy, quite correct.

To refer to RMS watts is meaningless.

Only amps and volts have RMS, Average and Peak values. The relationship between these values depends only on the waveshape over a complete cycle - sinewave, square, triangular, etc.

Power meters which use rectifier diodes + capacitor smoothing, eg., swr meters, respond linearly to peak values but indicate power on the assumption of a sinusoidal waveshape. The meter scale-graduations follows a square law and are cramped together at the lower indicated power levels.

The keywords in this subject are what a meter "responds to" and what it "indicates".

setup:
hp8640B generator with 100mv output to a
50 ohm termination at the hp3403C true RMS volt meter:

Without modulation: 100 mv (pwr= 0.2 mw)
with (about) 100% AM modulation : 122 mv (pwr= 0.297 mw)
=1.488 * unmodulated power.
QED
A mechanical coil meter or a simple detection circuit will indicate average
which is of course 100 mv, also when modulated.

?????? The last I read Motorola was getting ready to "deorbit" all the failed Irridium satellites and burn them upon rentry to the atmosphere, after the Irridium consortium went bankrupt due to pricing so high they couldn't attract enough customers to make it pay for itself. Even the cost orf maintaining the satellites in orbit was too much to bear, so they said. Has something changed?

Yes indeed. . Following an area code reassignment and split, now when I dial a town 40 miles to my east, there is a very noticable and annoying delay echo on the conversation that was not there previously.

Some hams use steel tubing for vertical antenna elements. Some engineers seem to believe that steel is not good antenna material due to its ferromagnetic properties, but that seems to ignore the fact that broadcasters routinely use in for their antennas in the form of large 1/4 wavelength steel towers, or those loaded to an electrical 1/4 wavelength, evidently without concern for this factor. I've used stainless steel cable for dipole antenna without any noticable deleterious effect. Many hams shunt feed their steel towers as vertical antennas and suffer no adverse affects from it.
Chain link fence top rail tubing comes in 20 foot pieces, swages together at the ends making it easy to use for any practical length of guyed masting or vertical element. It is available at any home center ans is much cheaper than any aluminum tubing.

Yes, plot the appropriate SWR circle on 50 ohms and the appropriate SWR
circle on 300 ohms. Where the two intersect is the correct impedance.
Since they intersect at two points, there are two possible solutions: R +
jX and R - jX.

The net power delivered to the 300 ohm line is 61.5385 watts (87.1795 -
25.6410). Therefore, 38.4615 watts is reflected in the 50 ohm line. The
SWR in the 50 ohm line is 4.27 and the SWR on the 300 ohm line is 3.37. The
two correct answers are 100 + j100 ohms and 100 - j100 ohms.

> http://www.mindspring.com/~w6rca

Cecil, your Smith Chart methods of impedance matching are valid, correct and not disputed. I would not suggest you change any of your slides or methodology. The points where we disagree are in the total re-reflection of power at the impedance junction and the scalar addition of power.

Let's use the wave reflection concepts that I have presented in this thread to see if we can come up with the correct solution to the example. It may not be as elegant as using the Smith Chart but it should prove my points.

1) Let's determine the magnitude of rho on the 300 ohm line. Pf at the load is 87.1795 watts. Pr at the load is 25.6410 watts. |rho| = sqrt(Pr/Pi) = 0.5423. Now we need to determine the phase angle of rho.

2) Let's determine the forward driving voltage delivered to the 300 ohm line by the source. The 100 watts of forward power in the 50 ohm line is equivalent to 71.7106 v. We will assume that this voltage has a relative phase angle of 0 degrees. The reflection coefficient at the impedance junction is +0.707. The total forward source voltage delivered into the 300 ohm line is 121.2183 v (71.7106 + 0.707*71.7106). Therefore, the total forward source power delivered into the 300 ohm line is 48.9796 watts. It is not 61.5385 watts. There is a significant difference between forward power and net delivered power.

3) Now let's determine the total forward and reflected voltages on the 300 ohm line. Since Pf in the 300 ohm line is 87.1795 watts, the total forward voltage in the 300 ohm line has a magnitude of 161.7125 v (we do not know the phase angle). Since the reflected power in the 300 ohm line is 25.6410 watts, the total reflected voltage on the 300 ohm line has a magnitude of 87.7058 v (we do not know the phase).

4) Now, lets determine the phase angle of all the steady state voltages in the system. How do we do this? We do this from knowing that Ptotal in the 300 ohm is found as follows:

Ptotal = P1 + P2 + 2 sqrt(P1) sqrt(P2) cos(T), where P1 is the forward source power delivered to the 300 ohm line, P2 is the re-reflected power in the 300 ohm line and T is the phase angle difference between the forward source voltage in the 300 ohm line and the steady state re-reflected voltage in the 300 ohm line.

We know that P1 = 48.9796 watts. P2 can be found as follows. The reflected power arriving at the junction is 25.6410 watts. It sees a reflection coefficient of -0.707. Therefore, the re-reflected voltage has a magnitude of 62.6470 v and the re-reflected power is 13.0822 watts. Now we have:

87.1795 = 48.9796 + 13.0822 + 2 sqrt(48.9796) sqrt(13.0822) cos(T)

Solving for T, we find two possible solutions: +60.2551 degrees and -60.2551 degrees. This is the phase angle difference between the forward source voltage in the 300 ohm line and the re-reflected voltage in the 300 ohm line.

5) Now let's determine the phase angle of the total forward voltage in the 300 ohm line. The total forward voltage in the 300 ohm line is equal to the forward source voltage + the re-reflected voltage.

Vf = 121.2183 @ 0 degrees + 62.6470 @ -60.2551 degrees (+60.2551 could be used as well - remember there are two solutions)

The phase angle of Vf is therefore -19.6538 degrees.

6) Now let's determine the phase angle of the reflection coefficient of the load.

We know that the steady state forward voltage, Vf, has a phase angle of -19.6538 degrees. Let's track this as we travel through the 300 ohm line. The phase angle of Vf arriving at the load is -19.6538. After reflection, the phase angle will have changed by X due to the phase angle of the reflection coefficient. The phase angle of the reflected voltage arriving at the junction will be -19.6538 + X. At the junction, the reflected voltage sees a -0.707 reflection coefficient, therefore the re-reflected voltage will have experienced a 180 degree have shift.

We know the phase of the re-reflected voltage is -60.5221 (determined above). Let's solve for X

-60.2551 = -19.6538 - 180 + X. X = 139.3987 degrees.

The reflection coefficient of the load is 0.5423 @ 139.3987.

Z = ZO (1 + rho) / (1 - rho) = 100 + j100 ohms.

73,
Steve

Bravo sir! The ARRL, no code international, and others have worked to
increase the new HAM population.
You in one "stroke" of genius have opened up amateur radio to a whole new
group of people.

You will find many on this newsgroup that will poo poo your ideas, I
encourage you to rise to the challenge and continue with your research.

Have you considered the attachment of sub wavelength flexible capacity hats
spaced approximately every 1/2 inch down the shaft of the proctenna? It is
this writers opinion that and increased sensitivity of about 17.3 dB would
be achieved.

Dear Kind Sir, may I inform you of a blatant patent infringement on my design... "The Rectal Flyer". My design is far superior as nothing has to be inserted from the south end. All that is needed to make the Rectal Flyer is to ingest small random pieces of wire.... and out it comes! Please note, this design, though far superior to the cheap copy... the proctenna, is not for the faint at heart. The key for first time builders is to try the 2 meter version first. The 80 meter version has been said to feel like passing a twisted sardine can!

Walter Maxwell" <w2du@journey.com> wrote in message
news:bAHC5.4126$mC.261654@monger.newsread.com...

The setup for the problem consists of a lossless transmission line of any length, with a characteristic impedance Z0 =1.0, terminated in a purely resistive load, R = Z0, and fed with continuous voltage V = 1.0 of frequency f. All energy available from the source is absorbed by the load. Thus, the initial current flowing in the load is 1.0 amp. We now connect a lossless transmission-line stub in shunt with the main transmission line at any place along the line. The stub can be either a l /2 line at frequency f, short-circuited at the far end, or a l /4 line at frequency f, open-circuited at the far end.

***

In order to understand what happens in the example presented by Walter, a very detailed and complex transient analysis of the transmission line system must be performed. Looking at only the steady state conditions, a correct interpretation of what is truly happening cannot be made.

In the steady state, there is a forward voltage of 1 v arriving at the stub junction (1 watt of forward power). There is a rearward voltage at the stub junction of -1 v (1 watt of reflected power). Hence, no *net* power is delivered to the stub junction. In the line connecting the antenna there is no forward voltage and there is no rearward voltage. In the stub itself, there is a forward voltage having a magnitude of 1 v (1 watt of forward power) and there is a reflected voltage having a magnitude of 1 v (1 watt of reflected power). Note the phase of the voltage in the stub line will vary with position in the stub line.

At the stub junction itself, the total voltage will be equal to 0 v and hence, the steady state line impedance will be equal to 0 ohms, a short circuit.

How does this all occur as a function of transient wave reflections?

The forward source voltage arriving at the stub junction sees the characteristic impedances of the stub line and the main line connected in parallel. The reflection coefficient at this point will be -0.33. The total source voltage developed at the stub junction will be +0.66 volts. This source voltage will be delivered as a forward voltage into the stub line and into the section of line connecting the antenna. At the same time, there is a reflected voltage of -0.33 v created in the main line. Now the discussion gets a bit more complex.

Let's look at the forward voltage delivered into the antenna line (+0.66 v). It arrives at the antenna where no reflections occur because the antenna impedance is matched to the main line ZO. (Don't gasp in disbelief quite yet)

Let's look at the forward voltage delivered into the stub line (+0.66). It arrives at the stub termination where a total reflection occurs because of the short circuit. This reflected voltage will arrive back at the stub junction and see the two sections of main line connected in parallel. The reflection coefficient it sees will also be -0.33. Now a re-reflected voltage will be created at this junction and travel back towards the stub

termination. At the same time the total voltage created at the stub junction will be delivered into the main line as a rearward traveling voltage and into the antenna line as a forward traveling voltage. This process of reflection and re-reflection in the stub line will continue until the steady state conditions are reached.

In the steady state, the total voltage delivered rearward into the main line as a result of the reflections in the stub line will be -0.66 v such that the total rearward voltage traveling in the main line is -1 v. The total forward voltage delivered into the antenna line as a result of the reflections in the stub line will also be -0.66 v such that the total forward voltage in the antenna line is 0 v, hence no steady state power is delivered to the antenna. The total steady state voltage developed at the stub junction is the forward source voltage + reflected source voltage + the reflected voltage from the stub line + the re-reflection of the reflected voltage from the stub line. +1 - 0.33 - 0.66 = 0 v, hence the steady state line impedance at the stub junction is 0 v and the effective steady state line impedance is 0 ohms.

73,
Steve VE9SRB

7 el Yagi is Fractal too. Everything is, don't you get it by now. It is patented, patent pending, or considered to be patented. All antennas belong to Freak, any publicity, reproduction or even pictures are ferbotten!
7 el. Yagi is fairly straight fractal, as soon as you have one bent in the antenna, it is Fractal Antenna Systems's property.
This threat is closet!

Another incoherent patent, referring to abandoned patent applications that cover anything from DC to light. What's next? Method of looking at the Fractals?

Sad and pathetic, and he don't get it, and looks like never will.

Hi Antenna Gurus,

I've been lurking here for months and got my General ticket about 3 months ago. I have a multi-band trap antenna about 25 feet up over my house and anchored on a live oak tree. I've used it to make some phone and CW contacts and recently I started experimenting with RTTY.

It seems that when I XMT with RTTY, it sets off an error message on my Jenn Aire range. This doesn't happen with CW or phone. I'm sending at 100 watts with a Kenwood TS 570-D and the antenna is maybe 20-30 feet at its closest point to the range.

My question: how can I keep the bleeping stove from bleeping every bleeping time I send RTTY? Thanks in advance.

Suggestion, if I may (no demands to be included in the patent):

Eat chili of the highest kind, and you will be able to produce Flyers that are so hot, that you will not need no stinkin propagation. Just don't light the match near by.

Hope it helps and have a nice day!

Put the blanket over it :-)

See if it is frequency sensitive, QSY around and switch modes, if no change than it is too much RF getting into the stove (and eating your power?). Either put filters or chokes on the line cord of the stove, or reorient the antenna. Or maybe PSK will be safer mode? RTTY is getting obsolete anyway.

Hi Dick,

Yes. But in this case no contract was entered into, except the moral contract of civil behavior and the Amateur code of open technical discussion.

No fraud was committed - except against that same moral contract, the standards of scientific enquiry, and OUR code.

Walter Maxwell" <w2du@journey.com> wrote in message
news:bAHC5.4126$mC.261654@monger.newsread.com...
From reading recent posts on this news group, it is evident that serious misconceptions still prevail concerning virtual open and short circuits on transmission lines, and whether total re-reflection of power can occur in impedance matching operations. My position is that both of these concepts are valid, and are the basis for the statements appearing in my book 'Reflections' concerning impedance matching.

Some posters on the NG deny that these concepts are valid, and therefore condemn Reflections for propagating incorrect information. An article has been published so stating.

****

One more minor point.

If you are only interested in knowing what the steady state conditions of any transmission line system are - forward voltage, current and power; reflected voltage, current and power; line impedance; delivered power etc, the concept of a virtual short circuit does not need to be introduced. Additionally, the transient behavior of the transmission line system does not need to be analyzed. The steady state formulas for line impedance and voltage and current on the line are all that is needed to perform a steady state analysis.

Hi Bart,

Much of what you describe about photonics is correct (and a surprising
entry - my only exception would be the loss of the mW/cm^2
specification). I've inhabited that side of the spectrum for years
and became used to the terms and measures you speak of. So used to
them in fact, that when I used the term RMS in relation to power I was
put on the carpet in much the same manner exhibited with this
side-topic.

It seems that at the low ends of the spectrum and the highest ends of
the spectrum RMS and power have some application. But lest we turn
this into a 600 posting monster debate, I am satisfied to talk about

vanilla flavored power.

Dennis,
I've heard of RF getting into a lot of things but a kitchen
range is a 'first'! It shouldn't be any different than any
other electrical device, except for size (big torroids). Use
ferrite 'beads' on the power cord, and maybe bypassing with caps.
All things considered, it may be easier to move your antenna
further away, either horizontally, or vertically (good excuse
for a tower). You might also ask Jenn Aire if they have any
suggestions. Love to see their faces, wouldn't you?

The price was based on being made on the Chinese labor market. After constructing a sample, the builder was hospitalized with a severe case of the bends. I am thinking of just selling a kit that would consist of a few meters of wire, 2 flower pots, and some PVC along with Frackkys web address. This would reduce the price by at least $411.27

If I ship the kit UPS it should arrived assembled and ready for operation!

Funny, I got the same answer without any wave theory. :-)

Let's take another example.

```
+-------------+
| |--->--->net 200w
net 100w--->--->| Black Box |
| |<---<---net 100w
+-------------+
```

Don't you think it's obvious from a conservation of energy
standpoint that the two 100w quantities are adding up to
the 200w quantity? Because these are scalar values, the
result would be exactly the same if we draw it like this:

```
+-------------+
net 100w--->--->| |--->--->net 200w
| Black Box |
+--->| | +---<---net 100w
| +-------------+ |
| |
+---------------------+
```

Source record: 178345

I live on the 14th floor of an apartment building and connecting a ground wire is virtually impossible. I want to hook up a counterpoise radial wire for the bands I work the most but have a couple questions.

I want to work 10, 15, 20, and 40 mtrs - do I need a separate counterpoise for each band or just one for the lowest freq (40 mtrs in this case)?

Must the wires be separated with some space between them or can I bundle them all together with tape into one long bundle to lay them out around the room?

Thanks for any help -

BJ

From: Walter Maxwell <w2du@journey.com>
Message-ID: <801D5.4520$mC.282580@monger.newsread.com>
Source record: 178349

OK Class, it's time to review the answers to the five-question quiz posed in my previous post. Steve answered them all correctly, and I'm sure all except those who are new to transmission line theory did also. So, for those less acquainted with the theory I'll explain the answers. For convenience the setup is repeated here:

The setup for the problem consists of a lossless transmission line of any length, with a characteristic impedance Z0 =1.0, terminated in a purely resistive load, R = Z0, and fed with continuous voltage V = 1.0 of frequency f. All energy available from the source is absorbed by the load. Thus, the initial current flowing in the load is 1.0 amp. We now connect a lossless transmission-line stub in shunt with the main transmission line at any place along the line. The stub can be either a l /2 line at frequency f, short-circuited at the far end, or a l /4 line at frequency f, open-circuited at the far end.

1. What is the amount of current now flowing in the load?

1.. 2.0 amp
2.. 1.0 amp
3.. 0.5 amp
4.. 0.0 amp
5.. None of the above
Answer: D, 0.0 amp

2. What is the line voltage at the stub point?

1.. 2.0 volts
2.. 1.0 volt
3.. 0.5 volts
4.. 0.0 volts
5.. None of the above
Answer: D, 0.0 volts

3. What is the line voltage l /4 toward the source from the stub point?

1.. 2.0 volts
2.. 1.0 volt
3.. 0.5 volts
4.. 0.0 volts
5.. None of the above
Answer: A, 2.0 volts

4. What is the line voltage l /2 toward the source from the stub point?

1.. 2.0 volts
2.. 1.0 volt
3.. 0.5 volts
4.. 0.0 volts
5.. None of the above

Answer: D, 0.0 volts

5. What occurs on the line at the stub point?

1.. Voltage and current are totally transmitted past the stub point and their energies are totally absorbed in the load.
2.. Voltage and current are partially transmitted past the stub point and partially reflected back toward the source.
3.. Voltage and current are totally reflected back toward the source.
D. None of the above

Answer: C. Voltage and current are totally reflected back toward the source.

The answers above occur because either of the two stubs establishes a short circuit on the line at the stub point. However, Steve said it's not necessary to consider the concept of a virtual short circuit, just basic transmission-line theory. As we proceed we'll see that whether the concept of a virtual short circuit is considered or not, the virtual short circuit is there, and it won't go away by simply not considering it.

Let's first define the virtual short circuit. The virtual short circuit (and the virtual open circuit as well) results from interference between two harmonically related electromagnetic waves. When their voltage amplitudes are equal and 180 degrees out of phase, and their current amplitudes are equal and in phase, the result is zero impedance at the point where the interference occurs. The effect of the virtual short circuit on the source wave at the stub point in the example is the same as if a hardware-type short circuit were placed at the stub point.

Before proceeding further let's examine how the wave interference at the input of the l /4 open-circuit stub establishes the (virtual) short circuit at the stub point on the line. I quote from my QEX article appearing in the Apr/May 1998 issue:

"Let us first consider the l /4 open-circuit stub. On arrival at the input of the stub, the source voltage and current are in phase, at which point we assign a reference phase of 0°. On arriving rearward at the input, the voltage and current waves reflected from the open-circuit termination of the stub have traveled 180° relative to those arriving at the input, 90° in traveling from the input to the open-circuit termination, and another 90° in returning to the input. However, keep in mind that, on reflection from an open circuit, angle q of the voltage reflection coefficient experiences no change, while angle q for current changes 180°. Thus, on return to the input, angle q of voltage waves reflected from the open-circuit termination is now 180°; a complete reversal in phase relative to the source. Consequently, the reflected voltage appearing at the input of the stub is of the opposite polarity to that arriving from the source. Continuing, with the 180-angle change in current on reflection at the open-circuit termination, plus the 180° travel on the stub line, on return to the input, angle q for the reflected current is 0°, in phase with the source current. So we have two equal voltages of opposite polarity at the input, the source voltage and the stub voltage, with their currents in phase. The result? Maximum current flow--zero impedance-a virtual short circuit. A perfect DC analogy is two batteries connected in series, plus to minus, and plus to minus-short circuit-maximum current."

With the (virtual) short circuit established at the stub point on the line we can now explain the answers to the five quiz questions.

Question 1. The load current is zero because the virtual short at the stub point prevented any current from flowing past the stub point.

Question 2. The voltage on the line at the stub point is zero because voltage must be zero where the impedance is zero. However, the current at the stub point is 2.0 volts because of the total reflection at the short circuit, as is well known in transmission-line theory. The action of the electric and magnetic field components in the electromagnetic waves during reflection are explained in detail in Reflections.

Question 3. The line voltage l /4 toward the source from the stub point is 2.0 volts. As the current doubles on total reflection at a short circuit the voltage goes to zero. At a point l /4 from the short toward the source the current goes to zero and the voltage is twice the value of the source wave. Typical standing-wave procedure when the reflection is total.

Question 4. The line voltage l /2 toward the source from the stub point is zero, because impedance, voltage, and current repeat on the line at every l /2 interval. Here we are repeating the conditions appearing at the stub point a l /2 away.

Question 5. The answer here is that voltage and current are totally reflected back toward the source, because the virtual short circuit at the stub point prevents any energy to pass. Following the law of conservation of energy, energy cannot be destroyed or made to disappear as if by magic. It has to go somewhere, and the only place it has to go is back up the line toward the source. Contrary to statements made by some of the posters, when waves cancel due to interference the energy in those waves is comprised of real voltage and current, and therefore the energy does not disappear as a result of the cancellation. Consequently, when two waves of equal amplitude and opposite phase mutually cancel, the first result is destructive interference, which forms the virtual short circuit. This is followed by constructive interference, during which the respective voltages and currents of the original waves combine in phase to form the re-reflected waves, emanating from total re-reflection at the virtual short circuit. The changing phase relationships that occur on re-reflection that cause the re-reflected voltage and current waves to emanate from the reflection in phase with the voltage and current waves from the source is explained in detail in Reflections. There are no 'phantom' waves unless an ethereal 'medium' scanning a crystal ball is involved.

I hope this discussion generates some feedback.

Walt, W2DU

PS--Steve has said the virtual short circuit need not be considered. However, he has previously declared that it doesn't exist, and that it cannot cause total reflection. He has made these statements in attempting to show the concepts I presented in Reflections are incorrect. I hope my discussion above clarifies the issue once and for all.

Hi Cecil:

It's all that wave theory that makes the Smith Chart and your calculations
possible. :)

Take care ..

Steve

I am most impressed with your announcement of a new antenna. The brief description provided augurs well for a revolutionary approach to effective communications. Let me encourage you further in your endeavors break new wind in the best tradition of amateur radio. Do not be discouraged by the skeptics, there are always naysayers that will attempt to dampen enthusiasm for any innovative effort. Be assured that their derisory attitudes simply reflects the constipation of their minds.

Allow me to suggest, that your approach brings to mind other attempts that did not meet with widespread acceptance and thus did not become useful fertilizer in the area of antenna dynamics. Specifically the developement 'antenna oil' also known as 'RF Grease'. The developement of which did not meet with much favor due to the necessity of frequent reapplication for full effectiveness. Weathering was its downfall, it just isn't practical to crawl out on your tribander periodically to apply a fresh coating of RF grease. However given the description of your antenna, it might be possible to store it in a sheathlike container that is filled with grease, and in fact if the sheath is made of a thin, non-conducting and non-pourous material the antenna might be used with sheath in place.

I hope that the above is encouraging to you.

Radio Al

P.S. If you wish to experiment with the 'rare' RF Grease, I do have available a small supply from the last military contract. This surplus is stored in 55 gallon containers, and weight approx. 107 lbs. I would need to ship via commercial trucking. Anyone else will be able to obtain it through my postings on Ebay. Look for "RARE-- RF Grease".

I accept PayPal.

Phil,

A model ordinance would have a big help in my experience with the City of Irvine, CA. My local government agency does not have clue. I asked the planning department what the rules were for amateur radio antennas. They insisted that I would be covered by the section of the zoning code that refers to "satellite dish antennas". When I asked what the rules were for TV antennas I was told that the same section applied. Unfortunately, this section of the zoning code makes absolutely no sense in regards to anything other than large satellite dish antennas. For example, a conditional use permit is required for any antenna which exceeds six feet in any dimension!

I seem to remember that to get average from rms, multiply by 0.9.

But, power is ExI (when they are in-phase and times cos theta when they are not). A positive voltage times a positive current gives a positive power, and a negative voltage times a negative current also gives a positive power (a minus times a minus is a plus).

A power graphic would look like the output of a full-wave rectifier in the simplist case.

When the voltage and current waveforms are sinusoidal, the power waveform doesn't look like a full wave rectified wave. It's a sine squared wave. A simple trigonometric identity shows that a sine squared wave has exactly the same shape as a sine wave. It's just twice the frequency, and offset such that the bottom just goes to zero. You can see by inspection that the average value of this wave is exactly one half the peak value.

Doing an RMS calculation on this power wave requires squaring it, taking the average of the squared wave, then taking the square root of the result. The square of the power wave is a sine wave taken to the fourth power, which no longer is sinusoidal. (But it still doesn't look like a full wave rectified wave.)

A 1% spread isn't very much. To maximize coding gain, you'd want to spread
the signal as much as possible.

>Here are the results:
>
>RESULTS:
>Frequency = 440 MHz
>Total transmit power = .01 watts
>Transmit spread = 5 MHz
>Receiver bandwidth = 1000 Hz
>Transmit power in 1 Hz = -56.9897 dBm/Hz
>Transmit power in 1000 Hz = -26.9897 dBm

Please note that this is the long term summed power in that bandwidth.
Long term being when the summation time is on the same order as the
length of the pseudonoise code. The instantaneous signal in this bandwidth
is a function of 1/N where N is the number of bits in the PN sequence before
it repeats. We are no longer prohibited from using very long PN codes.

To put this in another form, most of the time there is no interfering signal
at all in that 1 kHz bandwidth. Intermittently, there will be a blip as the PN code
hits this particular bin. In general, a NB receiver will *not* coherently sum these
blips, because it isn't synchronized to the PN sequence being used.

I also wonder a bit why you chose a 1 kHz bandwidth. That's too wide for
the current most common weak signal mode (Morse), and too narrow for
SSB voice. So the numbers really aren't representative (though they can
be scaled).

>Transmit antenna gain = 8 dBi
>Receive antenna gain = 8 dBi

>Received noise in receiver bandwidth = -96.30875 dBm
>Received noise in receiver bandwidth = S 6
>Receive system noise floor increase in dB = 41.69154 dB

Ok, now realize that a spectrum analyzer's noise floor is typically in the range of -80 dBm to -100 dBm. Resolution bandwidth and sweep speed will determine how much of the signal the spectrum analyzer will capture for display. In other words, it isn't always receiving a given frequency bin. That means the analyzer will see at best a signal 4 dB above its noise floor, and probably will see just a smooth slightly humped response over the spreading bandwidth because of analyzer resolution bandwidth and sweep speed limitations. That's what I claimed, and what I have observed at a reasonable distance from a CDMA source using a Tek 491 spectrum analyzer. (Reasonable in this case was 1/2 mile from a PCS cellsite.)

What a fixed frequency NB receiver will see is intermittent noise spikes, at rate proportional to 1/N. In a limiting FM receiver, that's probably inconsequential. That's what I've observed too. SS signals don't even open the squelch of NBFM receivers. (They do put a buzz on weak NBFM signals, but FM operation is typically done well above the FM quieting threshold.)

Depending on the AGC and noise blanker characteristics of a SSB/CW receiver, and upon the symbol lengths used for the NB signals being received, it may or may not present a problem. Worst case is when the NB symbol lengths are of the same order as PN bits. But the NB symbol lengths commonly employed (IE Morse code signals) are much longer than typical PN bit lengths.

SSB/CW type receivers are very much the minority on VHF/UHF amateur bands, well less than 1% of band usage employs this type of receiver. Nor is there any evidence that's likely to grow by much in the future. Two of our VHF bands already have more than sufficiently large CW exclusive band segments for this sort of usage, so I don't see this as being a big problem.

Even very good spectrum analyzers won't see a signal of this magnitude.

>efficient ones. And, to preseve the diversity of the ARS, we also will need to
>have some separation of some modes; SS and narrowband are generally not
>mutually compatible.

I addressed that above. I don't think that there is any serious problem for
FM operations, which are typically full quieting hard limited signals. SSB
and CW usage is so vanishingly small a proportion of VHF/UHF usage that
I don't think that's a serious issue either. Besides, there are exclusive band
segments already set aside for CW weak signal work on 2 of our bands, so
it is a moot point already there. Similar exclusive segments could be worked
out for the other bands if it becomes necessary, but I doubt that it would.
SS can also be a good weak signal mode. In fact it can be superior against
some weak signal propagation impairments such as auroral flutter and
libration fading. It might actually become the weak signal mode of choice
in the future if it is allowed free rein to develop properly.

Now SS has its own set of issues. I doubt very much that we'll see SS
systems replacing our NBFM repeaters for example. SS receivers don't
survive well in the high RF environments where we place our FM repeaters.
By their nature, SS receiver front ends have to be broad as the proverbial
barn. Coding gain isn't much help against fundamental overload.

Unable to take advantage of narrow cavity filters, it'd take considerably more
robustness in the RF front end of a SS radio to handle the signal levels commonly
encountered on those sites. I don't see much work being done in that direction in
the amateur community. That's too bad, because SS holds out the promise to
better utilize the spectrum currently tied up by FM repeaters which sit idle most

of the time, yet prevent other uses of the frequencies on which they are camped.

I actually see the most promising near term amateur application of SS to be for weak signal operations. That's where their coding gain and robustness against multipath and other forms of dispersive medium really makes them shine.

>the transmission line the instrument is calibrated for.

I think that is a potential problem, as well as the fact some solid
state low level modulated rigs limit the envelope to the peak power
detected in the ALC system.

My IC 751A is that way.

If you set the carrier for 25 watts and talk, the carrier has a
negative shift during modulation.

I can cure that by adding external bias on the ALC line and using it
to set the carrier level, and then running the power control on the
rig to full power.

When I run a DX100 that has been modified to have clean symmetrical
modulation I see a peak power four times the carrier power on my peak
reading meter. The thing that puzzles me is I see little or no shift
in power at all on my Bird meter, which is supposed to measure average
power. (Unless my memory is bad. I'll have to look again when I gather
up the energy to move that transmitter out of the closet.)

Don't know about the end fire array, but Hiram Percy Maxim of ARRL fame didn't invent the Maxim machine gun. That was his father, Sir Hiram Stevens Maxim, who was born in the U.S. but emigrated to England, where he became a naturalized subject and was knighted by Queen Victoria. HP was most known for the invention of the Maxim silencer, originally designed for rifles (and unusable on the pistols of the time) but later adapted to automobile mufflers.

His uncle, Hudson Maxim, was also an inventor who developed a number of advanced explosives used in World War I.

The calculation you describe gives the average, not RMS, power, although I don't dispute that it's commonly called "RMS power" in the audio world. (It's also common in the audio world to use speaker cable with alleged 8 ohm characteristic impedance to "match" the speakers.) Calling it RMS power doesn't make it so, though. If you actually do the RMS calculation for power when the voltage and current are sine waves, you get that the RMS value = 0.612 * Vpk^2 / R = (0.738 * V)^2 / R = 1.22 times the average value.

When you're dealing with audio amplifiers, apparently everyone knows that RMS power doesn't really mean RMS power, but average power. But this isn't generally true, so I recommend not using the term "RMS power"

to mean average power in other situations. You certainly won't see the term in engineering texts.

And this is one of several reasons why pending patents don't "cover"
anything or otherwise carry any legal weight. You never know what's
actually going to be patented until, and if, the patent issues.

490. Re: 75M mobile in a Jeep Cherokee - antenna help needed

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-05 00:00:00 UTC
From: jefff_b@my-deja.com
Message-ID: <8rhom4rko1@nnrp1.deja.com>
Source record: 178400

J.T.,

Within a week after picking up my new 2001 Jeep Cherokee sport, I put a new Icom 706MKIIG onto the side of the transmission hump, and drilled a big hole on the passenger side rear quarter panel just below the window for a ball mount. I use a hustler 75m resonator (the low power one), and it works just fine in this mounted position, along with one of those big springs off the ball mount. I put the two roof racks back at the rear, and use a short bungee cord to hold a plastic coat-hanger there, with the antenna mast going through it... this keeps the heavy mast/resonator from bending way down at high speeds. I have low branches in my neighborhood, too, but this setup works fine (albiet, noisy when it hits a branch.

I also have a 102" whip that I use for 10m on the ball mount, and it's around 13 feet at the tip, so there's lots of banging branch noise on side streets here in Massachusetts, but no problems anywhere on main roads. This bends at high speeds, too, but no need for the coat-hanger trick with it.

The bottom section of the hustler setup is supposed to resonate at 6m, but I've found that it interacts too much with the side of the vehicle when on the ball mount to be useful. I picked up another 6m antenna with a bottom loaded section, and an adjustable whip, however, that works fine on 6.

The first ball mount I used was a real piece of crap from HRO. I picked up the one that radio shack sells, and it's much more solid.

HRO did have a package of five quick-disconnects, though, that are decent, and I use these to pop whatever antenna I want to work with onto the Jeep, and also to have a quick way of getting the antenna off and out of sight.

As regards the engine noise, it's the fuel pump that gives you the constant high pitch rfi, and, of course, the spark plugs. With the 706, I have nearly complete absence of this rfi in SSB mode when I turn on the dsp noise filter, and the spark plug noise is also eliminated by the noise blanker. If you're going to work AM, however, the fuel pump noise and the spark plug noise will prevent hearing weak signals. Any strong signal on AM (S8 or better), however, will make the engine noise disappear.

If you have trepidations about cutting antenna holes in a vehicle, my experiences have been that it never caused a problem when trading the vehicle in, since a ball mount is not an expensive item to simply leave

on the vehicle when you get rid of it.

All things considered, the suggestion to put your current antenna on the roof will give you good results, although the antenna height may be a problem for you if you're mostly driving on side roads with low branches. Mag mounts also end up scratching up the paint, no matter what precautions you take over the long term. Also, the magnetic mounting, even the big four-bangers, can get whacked when given enough leverage from a really high antenna hitting a heavy branch.

My hustler setup has really worked well, though, and I'm very happy with it. It's versatility in accomodating different antennas with the quick-disconnect is really the best compromise I've found between performance and yet maintaining that "nothing of value in the vehicle at this time" look.

Good luck with your quest, and a big "ATTABOY!" for running such a fine American vehicle!

Your best bet to buy a good fringe-area antenna is Radio Shack. THey
have several models, graded according to distance. Believe me, you cant
make a better one for several times the $$$.
Hams seem to malign RS, but, really, there is no other near-universal,
"next door availability" source for lots of the goodies we need every
day, but dont seem to find in the junk-box.

Fractal element antennas are patented and patent pending.

My experience with other inventors is that when they write a highly documented and expansive application, and have a finite set of claims for that given patent, there are likely to be many, many other patents to follow which capture other pieces of that description.

If not, then the patent constitutes a publication and thus prior art--which prevents others from obtaining patents on that subject.

As to fractal antennas, there does not exist a non-fractal design that beats the MI2.

I will announce the FRACTAL ANTENNA CHALLENGE results shortly.

Hope this helps.

Walter Maxwell" <w2du@journey.com> wrote in message
news:bAHC5.4126$mC.261654@monger.newsread.com...
The setup for the problem consists of a lossless transmission line of any length, with a characteristic impedance Z0 =1.0, terminated in a purely resistive load, R = Z0, and fed with continuous voltage V = 1.0 of frequency f. All energy available from the source is absorbed by the load. Thus, the initial current flowing in the load is 1.0 amp. We now connect a lossless transmission-line stub in shunt with the main transmission line at any place along the line. The stub can be either a l /2 line at frequency f, short-circuited at the far end, or a l /4 line at frequency f, open-circuited at the far end.

Now for questions concerning what occurs after the stub is connected.

1. What is the amount of current now flowing in the load?

1.. 2.0 amp
2.. 1.0 amp
3.. 0.5 amp
4.. 0.0 amp
5.. None of the above
Answer: D - 0.0 amp

2. What is the line voltage at the stub point?

1.. 2.0 volts
2.. 1.0 volt
3.. 0.5 volts
4.. 0.0 volts
5.. None of the above
Answer D - 0.0 volts

3. What is the line voltage l /4 toward the source from the stub point?

1.. 2.0 volts
2.. 1.0 volt
3.. 0.5 volts
4.. 0.0 volts
5.. None of the above
Answer A - 2.0 volts
4. What is the line voltage l /2 toward the source from the stub point?

1.. 2.0 volts
2.. 1.0 volt
3.. 0.5 volts
4.. 0.0 volts
5.. None of the above
Answer D - 0.0 volts

5. What occurs on the line at the stub point?
1.. Voltage and current are totally transmitted past the stub point and their energies are totally absorbed in the load.
2.. Voltage and current are partially transmitted past the stub point and partially reflected back toward the source.
3.. Voltage and current are totally reflected back toward the source.
D. None of the above

Answer: The answer to question 5 is quite complex. All of the answers to questions 1 through 4 can be determined based on looking at only the steady state conditions as they are in fact, steady state answers. We do not even have to consider the concept of a virtual short circuit to answer these questions, just basic transmission line theory.

To understand what is really happening at the connection point between the stub and the main transmission line a transient analysis of the transmission line system is required. The issue is that no *net* power is flowing past the stub point. I.E, at the stub point, the steady state reflected power in the main line is equal to the steady state forward power in the main line. No net power is being delivered past the stub connection point. If you were to place a wattmeter between the stub point and the antenna, you would measure no forward power and no reflected power. If you were to place a wattmeter in the stub line, you would measure forward power and reflected power. They would be equal.

No Smith Chart or Smith Chart equations. Just voltage and power at the junction point. We'll do the Smith Chart later - that's an easy solution to the problem.

CATV 75 ohm hardline works well for me--3 230 foot runs so far and will likely add some more this fall and winter. No transformers. 1 run to a 2m/440 beam, 1 run to a 5 element 6 meter beam, and a run to a Cushcraft X-7 hf triband beam. All antennas have swr/bandwidth to factory specs and a tuner just flattens the line a bit more. Nothing over 2.1:1 You can make connectors from copper pipe fittings, hose clamps and double SO-239 connectors. Commercial hardline to PL-259 or SO-239 are available but expensive. Look hard for them at swaps--they are rare and don't stay out long.

If you want to be a purest--use transformer at each end of the hardline where you hook your coax jumpers, but then you are no longer multi-frequency.

What do you have for the "ground" or "counterpoise" in your yard, around your house, on your house? Copper sprinkler system? Chain link fence? Can you put out a readial system in the yard? Can you elevate a radial system? Does your antenna need to be "hidden" from CCR police? Inverted L over radials with SGC 230 coupler will give you good multi-band performance and be practically invisible.

You would need to access an autopatch on a local repeater and have the caller input the correct tones to open the squelch on your HT. It is not true "pager" of the sort that is normally carried on the waist and you pay a monthly fee to get "beeped" The page function is purely a tone thing to be used by hams calling hams that do not want to monitor all the chit chat on a repeater or simplex freq. If the repeater you are listening to mutes tones, you can't use the page feature on that repeater. Hope this helps.

> triangular, etc.

There are a few places where RMS power has application in engineering. For example, many types of optical detectors perform a conversion (transduction) between optical power and electric current. The conversion gain is called the responsivity and is usually expressed in amps of detector output current per watt of optical input. Sometimes the responsivity is expressed as the quantum efficiency which is output electrons per input photon. The two measures are easily interchangeable when the optical wavelength is known.

The detector output noise (rms amps / sqrt(Hz)) is often expressed as an equivalent input optical noise power. The so called Noise Equivalent Power (NEP) is expressed in RMS watts. The measurement of NEP and responsivity requires generating a source of optical stimulus whose RMS power is known.

Doesn't "patent pending" just insure prior patent rights to the patentee AFTER and only after a pantent is issued - IF and only if it is issued following all the investigation, serving as notice to all that the inquiry is in progress?

Not only that, is there anything that makes it a fraudulant activity of claiming that certain features are "patent pending" when they are not even a part of the claims?

Since the math is messy, let me say how it can be done. Conservation of energy says that there is 38.4615w reflected on the coax. That gives a reflection coefficient on the coax of 0.62 and a reflection coefficient on the twinlead of 0.54. We have an equation where Rho is a function of RL, XL, and Z0. Since the twinlead is one wavelength long, the virtual impedance is the same at the 50/300 junction as at the load. We now have two simultaneous equations and two unknowns, RL and XL, for which we can solve.

Of course, the intersections of those two SWR circles on the Smith Chart are the solutions. There are also probably two negative resistance solutions.

Steve, let me say that I was not trying to slay any of the sacred cows of EM field theory. I give presentations to typical ham clubs where I introduce the concept of matching an antenna system directly to a 50 ohm transmitter by varying the length of the feedline to effect a match without an antenna tuner (transmatch for the OOTC members). In order to convey the concept, I introduce the Smith Chart along with the SWR circle virtual impedance transformation. You can view one of my slides at:

http://people.delphi.com/cecilmoore/scswr2.gif

Would you have me throw that slide out and instead teach EM field theory in the two hour allotted time?

Besides all that, wouldn't one be exposing himself to liability in the form of a damages suit, and maybe harassment, for falsely claiming infringement or threatening others with action against their use of material that an alleged patentee claims to have under patent or pending, when it was not a valid or even claimed part of any patent application?

Looks to me like a certain Piddly Hippee Dee who reguarly posts here is operating under the old saw that the best defense is the first offense. Wonder when it'll all blow up in his face.

I have a 4 element, full size 20 meter bean for sale.

It's a Telex (Hy-gain) 204BA-S. 8.2 dB gain. The bean is build like a tank so it will withstand very high winds. If you want to put out a killer signal on 20 meters, this is what you need. Instrudtion manual included.

The beam is on the ground and ready for you to pick up.

The price is $175. It is in great shape.

The beam is located in the Denver Area.

73,
Bill

Don't forget that you want "seamless" tubing and not rolled.

It is difficult to find and quite often expensive.
For a mast I looked at some 2 1/2 inch OD tubing with 3/16ths wall X 24 feet long that was around $80, while the seamless version was $249.

1 1/2 inch seamless with 3/16ths wall was $157 and 2 inch with 1/4 inch wall was $157.50

Now, this is a lot heavier than the stuff used in antennas.
Most Aluminum used in antenna booms will have 0.058 wall and be slip fit with only about .004 clearance. Definitely no burrs, sand, or dents allowed.

you.

As long as the package is not oversize the freight shouldn't be too bad.

I just received two reels of Times Wire LMR 400 from Texas Towers. A thousand foot spool weighs 80#. and the whole thing was less than $40 as I recall.

Most of the antennas I've put together only use 6' lengths.
Remember that you can splint the stuff.

2" OD 0.058 wall is just right for 1.938 to slip in with 0.004 clearance
So two 6' sections can make a very strong 12' section. Some use as much as 2 feet of overlap, but you could easily get by with half that. Then ensert a 6' length of 1.938 in the end of that for 18 feet and so on.

It might cost a bit more in shipping, but using 8 foot sections which I believe can be shipped UPS would allow for much taller masts/verticals.

Years back Dentron made a 40 meter 1/4 wave vertical, but out of smaller diameter sections. I don't recall that they told us to use guys, but a few strategically placed nylon ropes did wonders.

The design was extremely simple with the base being a piece about 18 inches long with each end bent over to form a shallow C shape. There were holes drilled int he end and PVC pipe slipped over the aluminum tubing for insulators.

Yes there were shallow ribs stamped into the mount, but it was still simple and worked very well.

From examining the new patent- it appears that there is a fractal antenna patent, but , according to the claims, it is severely limited. As an example, unless I am reading it wrong, it only covers antennas having conductive material on BOTH sides of a substrate. Any antenna on only one surface, or of wire, is not even related.

The additional discussion covers LOTs of things, but, as has been pointed out, the claims are all that defines anything. There is some discussion in there that highlights the recent failed claims regarding the possibility of making a small antenna that beats the fractal version. (the failure being of the fractal version), and at least one claim concerned with the perimeter of the fractal that is obviously false.

It appears, from the list of abandoned claims, that what he got aint what he thought.

I wouldn't recommend putting ferrites inside the range unless you know exactly what you're doing. It's vitally important that no significant common-mode current should flow in the winding. Otherwise, the core will present an impedance to that current, and severe overheating of the core could result. This could cause a fire or violent shattering of the core. (I honestly don't know how much impedance you'd get from a typical core at 60 Hz, but at the currents involved in a stove, it wouldn't take much to cause a serious hazard.) When putting cores on a normal power cord, the potential problem is easily avoided by simply passing both conductors through the core(s) together. Inside the stove, the conductors are separated, and you'd have to make sure that any current-carrying conductor going through the core(s) is accompanied by one which always carries an equal and opposite current.

66 foot verticals are not easy under any conditions but I would definitely start with a lower end made from the 4" irrigation tubing and work down to smaller sections going up from there. There would be some machining of adapters involved between sizes of tubing which could get tricky unless you have access to a machine shop.
>

> What size tubing would I need? HOW DO I RAISE IT? Raising it would seem to
> be a key issue.

>
It would be a real pain in the butt. I've done it using trees and neighboring towers as a gin poles. A standalone true vertical antenna wouldn't be as much of a pain because the top ten feet or so could be a CB whip which weighs next to nothing but can't support anything, either.
>

> I would place the base on a 6x6 wood post (for insulation).
> If the thing can be made to work, I would want to add a coil and whip (with

>
You're actually talking about a tower, not a vertical antenna. If I was in your position I wouldn't even think about getting tangled up in a homebrewed tubing tower. I'd go right to the Rohn catalog and get self five sections of 25G with one being a base insulator section and maybe homebrew the top 16 feet from 6061 aluminum pipe.
>
http://www.rohnnet.com/CommPro/Towers/25g/25G.htm
>
Click on "Acessories" for the ceramic insulator section. You'd have to be very careful about not putting side loads on that section both during erection and wrt to wind loading else you break the ceramic insulators.
>
Wood is one of the worst of all RF insulators, virtually useless when supporting voltage-fed antennas.
>
There would be some money involved but in the end you'd have a much easier time

putting it up and have a much better and more reliable, longer-lasting structure. Might be that the money would turn out to be even-up, too.

Now be fair, Reg. I said only 1/4w makes it to the antenna and
I consider the radiation resistance to *be* the antenna, you
know, the part that radiates? I'm pretty sure I didn't say
only 1/4w makes it to the feedpoint impedance.

> Is the RG-213 more effecient than the RG8/U and if so how significant?
> I'm looking for very lo loss coax, apx 60 feet for VHF use.

Yes, RG-213/U is lower loss than RG-58/U, by a couple dB (for your 60').

However, since you want low loss for VHF, you might consider 9913/FX. It costs a bit more, as you might guess, but for your 60ft, it won't cost too terribly much.

Here are the loss characteristics of the above cables at 150 MHz...

dB/100ft

RG-58/U 6.2
RG-213/U 2.8
9913/FX 1.6

I've bought a couple of different cables (9913 for VHF, RG8 for HF) from a place called Cable-Xperts, and I've been real happy with them. They have fine customer service, too, if you want to just call them up and talk with them about what would work best for you. That's what I did, and I was pleased that they were willing to chat about my installation and give me a couple of different good choices, rather than telling me that I *needed* one particular thing. (See http://www.cablexperts.com/ or 800-828-3340)

best regards,

From: KI0MB <brnsmth@mo-net.com>
Message-ID: <strkjtcmi0du5b@corp.supernews.com>
Source record: 178178

I have put up a 40M Vertical and I am having trouble with it. It is a 1/4 wave with radials. It is cut to frequency as are the radials, but the SWR is about 2:1 and showing 75 Ohms at that level.

I am trying to figure out how to lower the SWR and impedance. Add more radials should raise the impedance, how do I lower it? Build a matching section of 75ohm coax? What is the best way in terms of efficiency.

Right.....it would seem to be sufficient to place them on all leads to
and from the range's control unit. This is the kind of thing that is
always iffy until you find what DOES work. It would seem to be simpler
to just move the antenna away from the house if that's feasable
That would also lessen other potential RFI problems.

Hi Brian,

Is it ground mounted? If it is, adding radials should LOWER (not raise) the impedance. If the 1/4 vertical really is tuned to resonance and then ground radials are added, you shoud see a feedpoint impedance of 37.5 ohms. You will probably need at least 16 radials to get anywhere close to the 37.5 ohm level. If you really are seeing 75 ohms on a ground mounted vertical, I would suspect one of two things:

1. The vertical is severely mistuned (it really isn't tuned to the point in the 40m band where you are measuring 75 ohms.)

2. You have incredible ground losses due to very poor soil conductivity and few radials.

What are you using to "measure" the 75 ohm impedance level and where are you making the measurement (at the shack or at the antenna itself?).

A properly constructed, fed and tuned ground mounted vertical with radials will show an input vswr of 50/37.5 or 1.33 to 1. If you really do see 50 ohms for a 1:1 vswr and the antenna is tuned to resonance, then the other 12.5 ohms is GROUND LOSS, which is NOT a good thing. So even though you see a perfect match, your antenna efficiency is suffering. It is as if you have placed a 12.5 ohm resistor dummy load in series with your antenna. It looks great, but it is NOT what you want. What you really want is a 1.33 : 1 vswr...now...you're not likely to get it to that level with 16 radials (laying on the surface or buried just below the surface), but you will reduce your ground losses dramatically with the 16 radials. The goal is NOT low vswr, the goal is a feedpoing impedance of 37.5 ohms. The closer you get to it, the more efficient your antenna system. The further away you are (including the magic 50 ohm value), the POORER your efficiency is. A perfect ground would show 37.5 ohms and an SWR of 1.33 to 1.

Additionally, when you have lots of ground loss, the antenna appears to be VERY BROADBANDED, i.e., the swr stays low over a very wide portion of the 40m band...for example you might see your swr stay at 1.5 to 1 for 3 or 400 khz (your stated measurement of 75 ohms = 75/50 , VSWR = 1.5 : 1)...because most of the impedance of your antenna system is just a resistor (30 or 40 ohms of ground loss). I'm still a bit skeptical of the 75 ohm value...I don't know if you can get that much ground loss, even with nothing more than a single ground rod for a ground. My bet is the antenna is not tuned properly. You need an antenna analyzer to do it right. Borrow one if you don't have one.

The radials for the ground mounted vertical need not be tuned, nor does it (practically) matter whether they are made of insulated or bare wire. It

doesn't matter much what size wire you use, either, as long as you have 8 or 16. They can be any length, however, it is suggested that they be at least 1/4 wave long (again, not critical). If you can't get radials that are 1/4 wave or longer, then put in more shorter ones. For example, 32 radials of random lengths, none as long as a 1/4 wave, will outperform 4 radials that are 1/4 wave or longer.

There is NO SUBSTITUTE for radials in a ground mounted vertical antenna, period. 16 would be my minimum, 32 would be my maximum. 120 may be the theoretical ideal, but the improvement you will see once you get to 32 1/4 wave radials is probably marginal at best.

If, on the other hand you are using elevated radials, they must be tuned or you can get all sorts of wild impedance readings. If the antenna is close to ground for hf (10 or 15' or so), then more than four elevated radials would be a good idea, but you can get away with 4...but they must be tuned to a 1/4 wave resonance.

Hope this helps. 73

If that was my RFI problem, at my house I believe I would first check to see if the supply wiring was accessable at the range, and if so, decouple it by choking the three conductor supply cable before it separates into individual wires, by using several ferrite rods, bundling them lengthwise around the supply cable with nylon wireties and tape. I'd use enough rods to completely surround the cable. Of course you need to be able to find the ferrite rods. I wouldn't imagine that any available ferrite could provide enough reactance at 60 Hz to cause a problem on a single wire, but of course I don't know that for sure either. Good point. If it was mine I'd probably try it to see how it warmed up.
In my (work) experience, one has to try different solutions until you find one that works. I've had such problems that were easy to cure and others that proved intractable.
One of the more puzzling was a public safety radio transmitter where a commercial FM broadcast station was built and put on the air less than a mile away. The FM station audio was somehow being demodulated in a public safety station speech amplifier and was being retransmitted. The cure was

really simple - I just wound a dozen turns of the microphone cable around a ferrite rod, before it entered the speech amp. It was only happening on one of two identical, side-by-side console operating positions, identical installations sitting side by side, identical speech amps etc. I still don't know how the audio speech amp was demodulating that 100mhz FM signal so clearly, I suspect it was taking place inside an IC in the speech amp.Why one and not the other? Never did answer that question.

Will, AA4NC wrote:
"Should I leave it unterminated to make it bidirectional, or terminate it to improve the performance to the northeast?"

A termination won`t improve performance in any direction. It only eliminates performance in the direction of the wire away from the terminating resistor. Terminating a Beverage antenna does not make it hear or talk any better in any direction. It only eliminates interference from or to the direction opposite the desired direction.

I lived 4 years in Portugal and regularly listened to WCBS in New York with my Beverage antenna. I used no termination. I listened after midnight local time in Portugal to New York`s evening news. Most of the Europeans had signed-off, so I didn`t have to worry about my back side.

The U.S. Army recommends the Beverage antenna as a transmitting antenna, saying it is the equivalent of a 1/4-wave vertical antenna over poor soil. The army likes the idea that an unobtrusive wire can be strung through bushes and trees and that it isn`t immediately seen by an enemy. Naysayers in this newsgroup say that tis performance isn`t the way the antenna models and that it isn`t the way it works.

Last night our ham club had a program on antennas. The ham presenting the program said his first antenna as a novice was a 2000 foot long wire strung through trees and bushes at an average height of 25 feet.(The army recommends high beverages.) Our ham worked 60 countries and made 1600 contacts with his Beverage antenna.

Hello group, I've been told that many of you cannot read my posts because I'm using HTML. I didn't realize I was using HTML--I know better than that. I composed my posts in Word, saving in rtf to maintain the columnar data intact. I sent the mail to myself through my Florida ISP and it returned here in Michigan intact, so I presumed it was ok. I've now discovered that rtf generates HTML I'm sorry it gave you trouble, so if you'll please stay with me I'll try to recompose my posts in a readable manner for the columnar data, and resend.

Thanks for your patience, because there is a very important issue here that needs to be resolved for everyone's satisfaction.

73 to all,

Walt, W2DU

Good points Roy. Let's take a closer look....

Assume 20 amps rms current at 60 Hz through a string of one or more Micrometals FT-50-75 cores. The cores have an initial permeability of 5000, an effective volume of 0.401 cm^3 and an effective magnetic path length of 3.02 cm.

The magnetizing force for a single pass is (cgs units to be consistent with the Micrometals catalog) H = 0.4 * pi * sqrt(2) * 20 / 3.02 = 11.8 Oersteds which will defiantly saturate most any ferrite material. In the MK system, 20*sqrt(2) (amps) / 0.03 (meter) = 943 (amps/meter).

Looking at the BH curve for type 75 ferrite material, the magnetic flux density at 11.8 Oe is about 3500 Gauss. In MKS, 3500 Gauss = 0.35 Wb/m^2.

The magnetic energy stored per unit volume of the core is B * H /2 = 0.35 (Wb/m^2) * 943 (amp/m) / 2 = 165 (J/m^3). In MKS, the effective volume of the core = 0.401 (cm^3) / 10^6 (cm^3/m^3) = 0.401*10^-6 (m^3). Therefore the total magnetic energy stored = 165 (J/m^3) * 0.401*10^-6 (m^3) = 66.2 * 10^-6 (J).

If we make a worse than worst case assumption that none of the magnetic energy stored in the core is returned to the 60 Hz circuit but is dissipated, then the power dissipated in the core = 66.2*10-6 (J) * 120 (Hz) = 7.8 mW which certainly would not create a thermal problem.

Note the above analysis is for a single turn. The core is already saturated with a single turn but the stored energy will increase proportional to both the current and the number of turns.

My concern would be that the core, which will may be carrying significant RF and 60 Hz current, will be switching in and out of saturation and will effectively AM modulate the RF at a 120 Hz rate and create a possible source of intermodulation distortion, especially a

concern when receiving.

539. Re: Virtual Short Circuits and Total Re-reflection

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-06 00:00:00 UTC
From: Walter Maxwell <w2du@journey.com>
Message-ID: <4WjD5.4677$mC.298178@monger.newsread.com>
Source record: 178188

Hello group, the following is a resent of my first post on thread. I converted to plain text and the columnar data appears to be ok here and hope it is with those receiving it. Again, apologize for sending in the wrong format, when I thought it was ok after testing it. I'll also resend my second post after I fix the problems in it.

From reading recent posts on this news group, it is evident that serious misconceptions still prevail concerning virtual open and short circuits on transmission lines, and whether total re-reflection of power can occur in impedance matching operations. My position is that both of these concepts are valid, and are the basis for the statements appearing in my book 'Reflections' concerning impedance matching.

Some posters on the NG deny that these concepts are valid, and therefore condemn Reflections for propagating incorrect information. An article has been published so stating.

So I propose a simple transmission-line problem, with five questions for the group's consideration to stimulate thinking that could ultimately reverse the position of the naysayers. I'm confident that everyone in the group will answer the questions correctly. However, if they answer the questions correctly, it will prove they consider the concepts of virtual short circuits and total re-reflection valid. The naysayers who answer correctly must merely rethink the semantics of the problem.

The setup for the problem consists of a lossless transmission line of any length, with a characteristic impedance Z0 =1.0, terminated in a purely resistive load, R = Z0, and fed with continuous voltage V = 1.0 of frequency f. All energy available from the source is absorbed by the load. Thus, the initial current flowing in the load is 1.0 amp. We now connect a lossless transmission-line stub in shunt with the main transmission line at any place along the line. The stub can be either a ?/2 line at frequency f, short-circuited at the far end, or a ?/4 line at frequency f, open-circuited at the far end.

Now for questions concerning what occurs after the stub is connected.

1. What is the amount of current now flowing in the load?
A. 2.0 amp
B. 1.0 amp
C. 0.5 amp
D. 0.0 amp
E. None of the above

2. What is the line voltage at the stub point?
A. 2.0 volts

B. 1.0 volt
C. 0.5 volts
D. 0.0 volts
E. None of the above

3. What is the line voltage ?/4 toward the source from the stub point?
A. 2.0 volts
B. 1.0 volt
C. 0.5 volts
D. 0.0 volts
E. None of the above

4. What is the line voltage ?/2 toward the source from the stub point?
A. 2.0 volts
B. 1.0 volt
C. 0.5 volts
D. 0.0 volts
E. None of the above

5. What occurs on the line at the stub point?
A. Voltage and current are totally transmitted past the stub point and their energies are totally absorbed in the load.
B. Voltage and current are partially transmitted past the stub point and partially reflected back toward the source.
C. Voltage and current are totally reflected back toward the source.
D. None of the above

Actually, the magnetic energy stored per unit volume is the intregral of
B(H)*dH evaluated from H=0 to H=Hmax. In the case of a linear magnetic
characteristic where B(H) is proportional to H, the intregral is simply
1/2 * Bmax * Hmax. In the limiting case where the core saturates with
very little excitation, the value of the intregral can approach Bmax *
Hmax, a factor of two greater than my original analysis. The actual
value can be determined by graphically integrating the BH curve and will
be somewhere between the two limiting values.

Actually the power dissipated could be as much as 2 * 7.8 mW = 15.6 mW,
still not cause for concern.

Source record: 178193

Hello group, I believe the following will come though correctly. I hope I haven't missed any portion that needed fixing. This is the material I sent in my second post. But since then I have received word from Steve that this material is different than that in re-reflection concerning impedance matching. This is not true, as I explain in detail at the end of this post.

OK Class, it's time to review the answers to the five-question quiz posed in my previous post. Steve
answered them all correctly, and I'm sure all except those who are new to transmission line theory did
also. So, for those less acquainted with the theory I'll explain the answers. For convenience the setup is
repeated here:

The setup for the problem consists of a lossless transmission line of any length, with a characteristic
impedance Z0 =1.0, terminated in a purely resistive load, R = Z0, and fed with continuous voltage V = 1.0
of frequency f. All energy available from the source is absorbed by the load. Thus, the initial current
flowing in the load is 1.0 amp. We now connect a lossless transmission-line stub in shunt with the main
transmission line at any place along the line. The stub can be either a half-wave line at frequency f, short-
circuited at the far end, or a quarter-wave line at frequency f, open-circuited at the far end.

1. What is the amount of current now flowing in the load?
A. 2.0 amp
B. 1.0 amp
C. 0.5 amp
D. 0.0 amp
E. None of the above

Answer: D, 0.0 amp

2. What is the line voltage at the stub point?
A. 2.0 volts
B. 1.0 volt
C. 0.5 volts
D. 0.0 volts
E. None of the above

Answer: D, 0.0 volts

3. What is the line voltage a quarter-wave toward the source from the stub point?
A. 2.0 volts
B. 1.0 volt
C. 0.5 volts
D. 0.0 volts
E. None of the above

Answer: A, 2.0 volts

4. What is the line voltage a half-wave toward the source from the stub point?
A. 2.0 volts
B. 1.0 volt
C. 0.5 volts
D. 0.0 volts
E. None of the above

Answer: D, 0.0 volts

5. What occurs on the line at the stub point?
A. Voltage and current are totally transmitted past the stub point and their energies are totally
absorbed in the load.
B. Voltage and current are partially transmitted past the stub point and partially reflected back toward
the source.
C. Voltage and current are totally reflected back toward the source.
D. None of the above

Answer: C. Voltage and current are totally reflected back toward the source.

The answers above occur because either of the two stubs establishes a short circuit on the line at the stub
point. However, Steve said it's not necessary to consider the concept of a virtual short circuit, just basic
transmission-line theory. As we proceed we'll see that whether the concept of a virtual short circuit is
considered or not, the virtual short circuit is there, and it won't go away by simply not considering it.

Let's first define the virtual short circuit. The virtual short circuit (and the virtual open circuit as well)
results from interference between two harmonically related electromagnetic waves. When their voltage
amplitudes are equal and 180 degrees out of phase, and their current amplitudes are equal and in phase,
the result is zero impedance at the point where the interference occurs. The effect of the virtual short
circuit on the source wave at the stub point in the example is the same as if a hardware-type short circuit
were placed at the stub point.

Before proceeding further let's examine how the wave interference at the input of the quarter-wave open-circuit stub
establishes the (virtual) short circuit at the stub point on the line. I quote from my QEX article appearing
in the Apr/May 1998 issue:

"Let us first consider the quarter-wave open-circuit stub. On arrival at the input of the stub, the source voltage and
current are in phase, at which point we assign a reference phase of 0°. On arriving rearward at the input,
the voltage and current waves reflected from the open-circuit termination of the stub have traveled 180°
relative to those arriving at the input, 90° in traveling from the input to the open-circuit termination, and
another 90° in returning to the input. However, keep in mind that, on reflection from an open circuit,
angle of the voltage reflection coefficient experiences no change, while the angle for current changes
180°. Thus, on return to the input, the angle of voltage waves reflected from the open-circuit termination is
now 180°; a complete reversal in phase relative to the source. Consequently, the reflected voltage
appearing at the input of the stub is of the opposite polarity to that arriving from the source. Continuing,
with the 180-angle change in current on reflection at the open-circuit termination, plus the 180° travel on
the stub line, on return to the input, the angle for the reflected current is 0°, in phase with the source
current. So we have two equal voltages of opposite polarity at the input, the source voltage and the stub
voltage, with their currents in phase. The result? Maximum current flow--zero impedance-a virtual short
circuit. A perfect DC analogy is two batteries connected in series, plus to minus, and plus to minus-short
circuit-maximum current."

With the (virtual) short circuit established at the stub point on the line we can now explain the answers to
the five quiz questions.

Question 1. The load current is zero because the virtual short at the stub point prevented any current from
flowing past the stub point.

Question 2. The voltage on the line at the stub point is zero because voltage must be zero where the
impedance is zero. However, the current at the stub point is 2.0 volts because of the total reflection at the
short circuit, as is well known in transmission-line theory. The action of the electric and magnetic field
components in the electromagnetic waves during reflection are explained in detail in Reflections.

Question 3. The line voltage a quarter-wave toward the source from the stub point is 2.0 volts. As the current doubles on total reflection at a short circuit the voltage goes to zero. At a point quarter-wave from the short toward the source the current goes to zero and the voltage is twice the value of the source wave. Typical standing-wave procedure when the reflection is total.

Question 4. The line voltage a half-wave toward the source from the stub point is zero, because impedance, voltage, and current repeat on the line at every half-wave interval. Here we are repeating the conditions appearing at the stub point a half-wave away.

Question 5. The answer here is that voltage and current are totally reflected back toward the source, because the virtual short circuit at the stub point prevents any energy to pass. Following the law of conservation of energy, energy cannot be destroyed or made to disappear as if by magic. It has to go somewhere, and the only place it has to go is back up the line toward the source. Contrary to statements made by some of the posters, when waves cancel due to interference the energy in those waves is comprised of real voltage and current, and therefore the energy does not disappear as a result of the cancellation. Consequently, when two waves of equal amplitude and opposite phase mutually cancel, the first result is destructive interference, which forms the virtual short circuit. This is followed by constructive interference, during which the respective voltages and currents of the original waves combine in phase to form the re-reflected waves, emanating from total re-reflection at the virtual short circuit. The changing phase relationships that occur on re-reflection that cause the re-reflected voltage and current waves to emanate from the reflection in phase with the voltage and current waves from the source is explained in detail in Reflections. There are no 'phantom' waves unless an ethereal 'medium' scanning a crystal ball is involved.

However, since this is a resend of the original, I have since received a msg from Steve saying that this treatment of a quarter-wave stub is different than the wave cancellation procedure I discuss in the impedance-matching mode. Steve and I have battled over this issue for weeks and weeks, but contrary to Steve's position, the two are the same. Wave cancellation is wave cancellation, no matter whether the phase relationships are 180 degrees, or some other angle. The resultants of the angles is the crux.

Steve insists that on wave cancellation both the voltage and current waves go to zero. This is not true, because the voltages and currents in reflected

waves are real, not reactive, and therefore the voltages and currents contain energy. If the voltage and current both went to zero simultaneously there would be no energy, but that energy cannot just disappear, it must go somewhere, and indeed it is re-reflected into the forward direction. The process of the wave interference begins with destructive interference, establishing the short cicuit, then constructive interference follows, establishing the redirection of the energy in the forward direction. This procedure is identical to that of a hardware-type short circuit, except that the short circuit established by wave-interference is a one-way short---transparent to the incoming source wave.

An example appears in my QEX article for Mar/Apr 1998, which discusses matching a 150-ohm resistor to 50 ohms. Here the reflection point is an open circuit, established by the following reflection coefficient angles. The load mismatch yields voltage and current angles of -60 and +120 degrees, respectively. The stub mismatch, which cancels the load mismatch reflections, has the voltage and current reflection angles of +60 and -120 degrees respectively. The angle of the voltage resultant is zero degrees and the angle of the current resultant is 180 degrees, thus establishing an open circuit. The energies in both sets of reflected waves are real, and cannot disappear. They are redirected in the forward direction during the constructive interference following the destructive interference that established the virtual open circuit. There is no fundamental difference in this procedure that established the open circuit than that in the open-circuit quarter-wave line that establishes a virtual short circuit at its terminals.

The crucial point to remember concerning reflection and re-reflection is that the energies in the voltages and currents in the reflected waves cannot disappear, and for this reason the voltage and current in the reflected waves cannot both be zero simultaneously on cancellation, only one or the other at a time. Reference to transmission-line theory books concerning reflection of electromagnetic waves will verify these statements.

In addition, I have had experience as an RF engineer in RF laboratories for more than 50 years, 31 years at RCA Laboratories' Antenna Lab, and 20 years in my own RF lab. During this time, I've made thousands of hands-on RF measurements on many different transmission-line circuits, including that of the example in my QEX article. These measurements corroborate the concept I discussed there, including the angles of the respective reflection coefficient angles I presented above.

"The stub can be either a 1/2 (WL) line at frequency f, short-circuited at the far end, or a 1/4 (WL) line at frequency f, open-circuited at the far end." (Either makes a virtual short.)

The 1/2-wave line repeats an impedance. The 1/4-wave line inverts an impedance. The non-believers should try to explain radar antenna switching as accomplished with gas tubes and tuned line sections. Virtual opens and shorts are the bases of this switching.

Bart, thanks very much for doing the calculation. I'm so used to using low frequency ferrite cores at HF, where they're very lossy and present an essentially resistive impedance, that I failed to realize that the loss is probably negligible at 60 Hz. I'm sure your calculations are close enough. So I concur that it's probably not dangerous to use at least cores with a single turn on single 60 Hz lines, but that it might have undesirable RF effects.

If I were attacking that problem, I'd probably work on choking the DC supply and other lines coming into the electronics board which is being affected. Because it probably doesn't have to respond quickly to external stimulii, fairly heavy bypassing would also be possible and helpful.

Renee,
You're going to have problems getting an RF ground, there's
just no way around that being on the 3rd floor, with a random
wire antenna. Maybe your best bet would to use a counterpoise
tuned for each band of use. Doing that, it's 'best' to spread
them out away from each other, or changing them when switching
bands.
The screw, or third wire ground on an outlet 'should' be a
good electrical ground. An RF ground? Probably not so good.
The same for a radiator. Both, since they become part of your
antenna system, will introduce RF into the building. It may
not be objectionable, but then again, the odds are in favor of
it being a nightmare.
When you're not on the ground floor, a balanced antenna of
some kind is much easier to 'handle'. You may still find that
you have an RF problem, but it isn't as likely as with the
random wire.
Good luck...
'Doc

> VA3GX

Losses for R-H100

Frequency Loss per 10m of cable
28MHz 0.20dB
50MHz 0.25dB
100MHz 0.35dB
400MHz 0.82dB

Losses for RG-213

28MHz 0.36dB
50MHz 0.45dB
100MHz 0.67dB
400MHz 1.47dB

Losses for Mini RG-8

28MHz 0.69dB
50MHz 0.86dB
100MHz 1.28dB
400MHz 2.82dB

Losses for RG-58CU

28MHz 0.78dB
50MHz 0.97dB
100MHz 1.40dB
400MHz 3.00dB

It would seem that RG-213 is almost twice as efficient as RG-8.

Currently I have mainly 15 to 20 metre runs of RG-213, which is a reasonable trade off of cost per metre over loss, but if money were no object, or your shack is some distance from the antenna, then R-H100 would be your best bet.

The only downside to the physical routing R-H100/RG-213 cable is its lack of flexibility in comparison to RG-8 or RG-58CU, but you get used to things like that.

Before you buy, do check out the other cabling specifications mentioned in this thread.

I haven't waded through all the other posts in this thread;
perhaps someone has already suggested this: put your 100W
carrier into a dummy load and measure the temperature rise
after it's reached thermal equilibrium. Now modulate it
(100% with a sinewave) and re-measure the rise. You should
see that the power dissipation in the load really has
increased. As others have mentioned, if you measure the
RMS output voltage and current, you'll see an increase in
each under modulation. Typical ham SWR and power meters
do not measure the RMS values.

(re: "RMS power" in audio amplifiers. I've always taken
that to simply be a contraction/simplification to mean
the (average) power under simple sinewave excitation.
You'll find such simplifications in a great many different
fields, and indeed in every-day language useage. For
example, "need" is not something felt by inanimate objects,
but we'd commonly say something like, "My car needs gas."
And others wouldn't question what we really meant: "I
need to put gas in my car so I can drive it a bit further.")

Cheers,
Tom

I think you are confusing the mini-rg-8 with the regular rg-8. Mini 8 is
not near as good as rg-8. "quite a bit smaller" . RG-8 and 213 have the
same loss. They are the same size. They look and act the same, the only
difference is the mil spec shield and the better jacket with the 213. MK

>As to fractal antennas, there does not exist a non-fractal design that beats the MI2.<

Finally got a look at Steve's files and read the commentary regarding alternative geometries to the MI2. The first thing I noted was Steve's decision to make the two high-current portions of the loop straight and optimally separated. Good move!

In the case of loop #3, significantly more wire was needed to resonate the loop, but--ironically--the resultant resistive losses appear to have worked in Steve's favor. He obtained a higher feedpoint impedance (41.4 ohms) and improved bandwidth (2.14%), while paying no appreciable penalty in gain.

Now, here's a puzzler. Why was there no gain penalty?? If Steve's #3 loop showed gain equal to the MI2 while simultaneously exhibiting significantly higher wire losses, doesn't that prove the MI2 shape is LESS effective as a radiator than a quad using straight and optimally separated conductors in the highest-current segments of the antenna?

Same signal strength, twice the bandwidth, and connected directly to your 50-ohm rig without matching loss. Go figure?

By way of history, two-dimensional loading schemes for the quad loop are nothing new. Andy Pfeiffer, K1KLO, built a linear-loaded 12-meter quad around 10 years ago. Not long after, Paul Carr, N4PC,
authored the "Squad", a 17-meter linear-loaded quad with 10-meter dimensions in the early 90's for CQ.

Prior to building the two-element version, Paul built an experimental single quad loop yielding a near 50-ohm feedpoint and modeling less than 1-dB down from full size. Paul used a diamond-quad shape fed at its base and loaded by four-wire meander lines extending inward from each of the two horizontal corners. He claimed +5 dBd gain (calculated) for his two-element "Squad".

I remember that antenna he had. I've known Kevin for 30 years. You should have seen the arcs he could draw off that thing in bad weather. 2-3 inches or more. But I always considered that antenna a long wire more than a beverage. Sure, about the same thing wire wise, but I don't think his acted quite like the normal beverage used for low band receiving. If I remember right he used it the most on 15m, but other bands also. He seemed to get a fair bit of gain on 15m lengthwise with the wire. MK

>guts to tackle.

The bill covers LOCAL zoning and planning decisions/codes, and
in its operable parts is a 100% duplication of the FCC's PRB-1
wording. The only thing that it and its counterparts in other
states do thst PRB-1 does not do is to set a minimum antenna
structure (tower) hight under which the planning/zoning folks
must grant the permit as a matter of right.

The main reason for having such a statute on state-law books
is that zoning/planning folks get their hackles up when folks
like me hit them between the eyes with PRB-1 -- "we don't care
what the $%^%^ Feds are trying to tell us to do" -- whereas
citing state law requirements is more easily acccepted because
(a) the local municipality is a subdivision of the state, not of
the Federal government and (b) they are used to using state law
standards and requirements in their daily business.

Another benefit is to have uniform requirements amongst the
various communities of the state. Much as those of us who are
Fed-ists would like to see this nationwide, it isn't going
to happen.

> Answer: C. Voltage and current are totally reflected back toward the source.

In the steady state the stub presents a zero impedance at the junction, just as the Smith chart and the transmission line equations predict. It is a cancellation of forward and return waves on the stub. This zero impedance is just like any other zero impedance. It creates a backward wave and a standing wave on the main line, just like any other short circuit. The difference is that the *actual physical* short circuit does not actually occur *across* the main line right at the stub point-of-connection. That is why it is a "virtual" short circuit.

So what is the point of this obvious and simple exercise? Are we supposed to extrapolate that into something more cosmic?

Also, I am not a "student" in anyone's "class" and don't want to be patronized in that manner.

Hasan already covered about everything, but I'm also wondering about the 75 ohm feed. I bet it's really the other way, and about 25-35 ohms, unless something really weird. Myself, I've never had to use a matching device on any 1/4 vertical for 40m.It was close enough for gov work, but I've seen a few 1/4 wl ground planes that use a hairpin to get a good match. But those usually for higher bands, cb, etc. With the elevated 40m gp I ran, I adjusted the match by tweaking the radial lengths. Much easier than lowering the antenna to adjust the radiator. With the ground mount I adjusted the radiator. You could use a small coil at the base to match much like a mobile type setup.Usually, the most drastic thing you will notice adding more radials is a reduction of bandwidth. And that can be used as a good indicator of saturation of you are really hard core. Once you get to the point that adding more radials does not decrease bandwidth, you have enough for all practical purposes. But this can take many for a ground mount. Don't give up on it . It'll be great for 40 dx. Also you could probably add a cap at the base and run as an appx 3/8 wave on 30m. Would work well. The cap would tune out the reactance. MK

Not exactly true. By "eliminating performance" away from terminating resistor it improves significantly F/B ratio, eliminating much of noise from that direction, therefore improving signal to noise ratio, therefore allowing to hear more weak signals from the direction towards the terminating resistor. If you phase two or three beverages in either broadside or staggered fashion you further improve the pattern (F/B and S/N), and be able to hear weaker signals. So it depends what are you after, one antenna for both directions or super ear for one direction.

OK Bill, I'm sorry you feel 'patronized', so I guess my attempt at humor on this NG is not appreciated, so I'll desist hereafter. This was my second ill-fated attempt at humor, sorry.

The point of this simple exercise Bill, is that some people in this thread say it ain't so, that a virtual short circuit cannot exist. They say for this reason the basis for my explantion of impedance matching using reflection mechanics is invalid, therefore my position in Reflections is wrong. I am again attempting to defend my credibility.

Your explanation of the difference between a physical short and a virtual short is evidence that you agree that a virtual short is factual, and not simply a figment of my imagination, contrary to the aforementioned people in this thread.

> Yes, RG-213/U is lower loss than RG-58/U, by a couple dB (for your 60').

Ooops! I mis-read your post... saw RG58 when you said RG8. Sorry. (End
of a 17 hour shift for me.)

> Here are the loss characteristics of the above cables at 150 MHz...

> dB/100ft
> --------
> RG-58/U 6.2
> RG-213/U 2.8
> 9913/FX 1.6

Add to this list:
RG-8/U 2.3

So, at VHF, the two cables you asked about are nearly the same from a loss
per unit length point of view, with 213 have just a little more loss.

571. Inv-V or Vertical?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-06 00:00:00 UTC
From: David <k4zzrNONSPAM@gate.net>
Message-ID: <8rlfmi$1ncg$1@news.gate.net>
Source record: 178270

In addition to my tribander, I'd like to put up an omnidirectional antenna for 40 and 20 meters, so I can hear what's going on behind me rather than turning the beam. Given the choice between an inverted vee or a vertical, which would be the least prone to RFI?

I could probably only get the apex of a Vee up to about 25 feet and that would be by hanging it from an arm off the aluminum crankup tower.

Otherwise, I could mount a vertical to a metal pole on the side of my shed about 50 feet from the radio room to get it up in the air a bit. I'm surrounded by trees (not very big ones) here in Florida and figure it would be good to get the vertical up in the air? If I went with a multiband vertical I suppose I'd have to put in several ground radials, but I've heard mixed reviews on the "groundless" verticals, anyone got one of these and are you happy with it?

Any advice is good advice,

David, K4ZZR

My agreement with you regarding this particular example should not be construed as a blanket endorsement of all of your ideas regarding wave mechanics and conjugate match. I just simply cannot go along. The factuality of this example should not be extrapolated beyond itself.

Second-iteration Minkowski Island, off the top of my head and without bothering to look it up. Even bent up a couple of them awhile back.

>There are lotsa MI2 shapes.<

I'm familiar with one MI2 shape.

>This statement of your is wrong.<

Are you referring to my puzzler? Perhaps someone will jump in and straighten me out. I'm having a little problem with AYEM modulation at the moment, too, but I'm making progress.

>I have an MI2 here with an impedance of 52 ohms with j1.0 according to the MFJ thingie.<

Have we seen that one? I hope you're not holding out on us.

>Wasn't Paul Carr the guy you Comm Quat folks paid to write junk science articles?<

That would be Joe Carr, a somewhat more widely-known and internationally famous professional writer who also gives excellent seminars to industrial and government procurement specialists on how to spot bullshit artists and flim-flam in the technological marketplace. Not to take anything away from Paul, of course, who's built some nifty antennas, writes well, teaches electronic theory, and is a great guy with an active interest in QRP.

>You still haven't been able to show Chip's statement is wrong.<

Well, no big thing. But, if you see him, please let him know I'll try to give it some more thought!

Hi David--

I think I'd use a vertical for a spotter antenna. If nothing else, it has lower angle for picking up DX. Also, it will be cross-polarized with your horzontal transmitting antenna and less apt to bring dangerously high RF levels into the shack.
"Groundless" verticals are okay on the higher bands as long as you get them up in the air. Keep it as far from your transmitting antennas as you can.

The basic tower/mast/vertical raising technique has been in use around here for decades and is known as "Gerry's Trick", named after Gerry Mathis w3bes/w3gm, one of the premiere contesters of all time. He had huge antenna farms and used the tiltover gin pole method for raising 100-180 foot heavy towers loaded with huge Yagis.

Thank you both for the comments. Based on the comments my conclusion is that a 60+ vertical is not just a length of light-weight aluminum (as I had hoped). For anyone else thinking along the same lines, the site http://www.karlquist.com/Irrigation/irrigation.html is very interesting.

I will probably stick with my original plan of a 40' tower (probably the aluminum variety) with a lightweight mast on top of it. I was looking for alternatives partly to avoid (or to try to avoid) a need for building permits, etc, etc. A tower is sufficiently permanent that it probably needs a building permit.

What is probably happening is that your resonant feedpoint resistance is
around 35 ohms and is being transformed to 75 ohms by the feedline.

Run a plot of SWR every 50kHz from 7.0 to 7.3 and tell us what the
results are.

Yep, I remember using it on 80 and 40 also, but don't remember it being much different than any other dipole for those bands. IE: wasn't really a dx killer. But on 15 it seemed to do pretty well. He used to hear alot of africa , eu, etc on that thing that I had trouble hearing on the low 40 meter dipole I had. He made it from real thin wire. I remember one time going over there to help him repair it after a storm. It ran across a large field. We got our tickets at the same time at the old HARC on lozier street. He got his one week, and I got mine the next week. In those 7 days, the calls went from his wd5bqz to my wd5cjl. They were really churning em out in those days. "1977". Those were the big CB craze days and lots drifted into ham radio around that time. I got into ham radio in 1971 and learned the code, etc, but kinda drifted out and didn't get legal until 6 years later. MK

That should answer many of your question and also explain why they
prefer that you don't ground nor add radials to the antenna.

That was the reason for suggesting placing one on each AC lead-they
aren't too big. Some ranges don't use a large cable, but are hardwired
with #10 Romex. Each conductor can be separated and made availabe for
individual choking.

The problem of course is on the control board. Isolating it by choking
its power input and control output leads MAY solve the problem, then it
may not, depending on the magnitude of the interfering signal which is
almost certain to be coming into the range via the AC power leads. It
might be necessary to head off the RFI farther away from the control
board than to choke at the board itself. The RFI could still radiate
into the control board. There are too many variables to be sure of a
cure without personally investigating the range.

Some such prolems are easy to cure, others nearly or in fact impossible
with any available practical method.

Dick

Who said a 2:1 SWR was evil? I'm just trying to understand why an antenna
that is supposed to have a feedpoint impedance below 50 ohms is "showing"
an impedance of 75 ohms.

Rick,
Wow! This is the best GA design that I have seen to date, can we adapt the design a bit and not use plastic trashcans but metal instead, this will provide a great foundation for a low band CFA.

BTW a stellar authority in the field informed me that small lot hams do tend to suffer from many problems and one of them can be a small schmecky. I wonder if this deficiency explains the attitude in sharing intellectual property with fellow hams.

For RF purposes consider the pair of wires to be one wire.

Wind the twin antenna wires, both together, a lot of turns round a ferrite rod to make a choke. A suitable ferrite material is as used for MF receiving antennas. The ferrite is not magnetized because the DC is in 'balanced-mode' and cancels out. One side of the DC supply can be grounded at the cold end of the choke if you wish.

If necessary, to isolate the DC from the tuner or transmitter, feed RF power into the hot end of the choke via a capacitor which need be capable only of carrying the RF current. Also connect a 0.01 uF capacitor between the two wires at the hot end.

At the relay end of the pair of wires, as a safety precaution, connect a 0.01 uF decoupling capacitor across the relay operating coil.

The foregoing applies to an end-fed antenna using one relay. For a centre-fed dipole and two relays (which I havn't tried) another choke would be needed at the feedpoint unless the balanced feeder was constructed from 2 times 2 = 4 wires. But on contemplating such a construction one might be tempted to revert to a pair of good, old fashioned antenna traps. ;o)

Here's a brief derivation of the energy stored in a linear or nonlinear inductor comprised of one or more perfectly conducting turns around a toriod core. Flux outside of the core may contribute significantly to the stored energy once the core material is saturated, but is not considered here. Eddy current losses are ignored but the method can be used to calculate hysteresis losses if the integration is performed over an entire excitation cycle.

Variables:

N = number of turns
A = cross sectional area of core (m^2).
l = effective magnetic path length = pi * mean diameter of magnetic core (m)
i = current through inductor (A)
v = voltage across terminals of inductor (V)
H = magnetic field intensity (A/m)
B = magnetic flux density (Wb/m^2) = (volt-seconds/m^2)
t = time (sec)
P = power input to inductor = dW/dt (J/sec)
W = energy stored in inductor (J)

d = differential operator. e.g. dB/dt is the time rate of change of B

The voltage drop across the inductor is: v = N * A * dB/dt

The power input to the inductor: P = v * i = N * A * i * dB/dt

For the toroidal magnetic circuit: H = N * i / l

Substituting N * i = H * l :

P = H * l * A * dB/dt

The total energy is : W = integral(P * dt) = A * l * integral(H * dB)

The classic BH material characteristic curve gives B as a function of H. The slope of the BH curve is, by definition, dB/dH and leads to the observation that the value of the above integral is the area between the B axis (H=0) and the relevant portion of the BH curve.

Eyeballing the BH curve for type 75 (J) ferrite material, I estimate the value of the integral from H=0 to H = 11.8 Oe (from the previous post) to be approximately 1000 Gauss - Oersteds which in MKS is 7.96 (J/m^3) as compared to 165 (J/m^3) in my earlier analysis which incorrectly assumed a constant permeability of Bmax/Hmax.

It might be worth noting that the same calculation done for a typical powdered iron material would result in much greater stored energy then in the case of the ferrite analyzed above. Additionally, powdered iron is capable of maintaining it's initially lower permeability at much greater magnetic field intensities and may do a better job of decoupling conducted EMI in cases similar to the one being discussed.

Bill, I can't believe you mean that no reflection can occur at the stub point in my example where the quarter-wave open circuit stub is in shunt with the line. Are you saying no reflection can occur there unless a physical short circuit is placed there? Are you then also saying that no reflections can occur as a result of wave interference? I can't believe you mean that.

> Z0-match.

A way to see this problem is the following:

Imagine a line that is several wavelengths long. The far end is terminated in a short circuit. This is a "hardware short circuit".

If we look along the length of the line, we see a zero impedance at each halfwave point *toward* the generator. Each one is due to a phase cancellation of a forward wave and a reflected wave.

Each of these zero impedance points is a "virtual" short circuit.

Each virtual short circuit is created by the *single hardware* short circuit.

A forward wave from the generator is not reflected by each and every virtual short circuit. Only the *hardware* short circuit actually produces the actual reflections and therefore *all* of the virtual short circuits.

How can we prove this? A logic trick will do it. Suppose that the first virtual short is in fact a perfect reflection point. Then all of the forward wave will be reflected from that point and *nothing* will, by definition, arrive at the far end.

The conumdrum is that if all of the wave is actually reflected at the virtual short, and therefore no wave reaches the far end, then the virtual short cannot even exist. In other words the virtual short *owes its existence* to the hardware short at the far end and to the forward wave that is reflected from that hardware short circuit.

The mental difficulty is the following: If we look at a section of line to the generator side of a virtual short we see a standing wave pattern that is *identical* to what it would be if the virtual short were in fact an actual hardware short across the line at that same point. In other words the line to the left of the virtual short is identical to that due to a real short.

This is a seductive idea that encourages the belief that the virtual short is in fact a point of reflection. But a little thought shows that it is all *smoke and mirrors* in the truest sense. A mind game that looks OK but is in fact, nonsense. The thing that is bothersome is that some good folks are obsessed with this cockamany idea.

The way to get out of this difficulty is to realize that the virtual short *must* have a reflection from the real short, and cannot itself be an actual source of reflection.

This is exactly the same situation as in Walter's example, where the virtual short is due to the stub and it is due *only* to a phase cancellation of forward and reflected waves within the stub, which is a shorted 1/2 wave or an open 1/4 wave. In both cases the far end of the stub is a perfect *hardware reflector*.

Steve, you need a refresher course on the principles of wave interference to see what happens to the energy in the waves at the interference point. You will discover that a virtual short circuit is a virtual short circuit (or an open circuit) and is established wherever the wave interference occurs, including, but not limited to the terminals of an open-circuited quarter-wave stub.

> What is physically happening at this junction point is quite complex and
> cannot be fully appreciated by looking at only the steady state
conditions.

Steve insists that the evolution to the steady state from the initial state is important. However, the evolution to the steady state is already well known. I is not necessary to evolve something that is univsersally known.

Not so. Steve is forgetting that we are discussing conditions at a totally reflecting discontinuity. It is a fundamental fact that when a wave arrives at a total discontinuity, either the voltage or the current goes to zero while the other does not. The voltage goes to zero and the current doubles

at a short circuit, and the current goes to zero while the voltage doubles on arriving at an open circuit.

A
> traveling wave cannot have 0 voltage with some current nor can it have 0

>
> In the particular case of impedance matching, a situation occurs where two
> (multiple) waves traveling in the rearward direction combine to a net
> rearward traveling wave of 0 voltage and 0 current.

This statement is totally untrue. When two such rearward traveling waves are in motion toward effecting an impedance match their respective phases are always complementary on arrival at the matching point. At this point the resultant phase angles of the respective voltages and currents in the waves are either zero for voltage and double for current, or vice versa. The voltage and current can never go to zero simultaneously without violating the law of conservation of energy, because there is energy in those waves that cannot just disappear. Remember, we're talking about virtual open or short circuits here, total discontinuities that Steve refuses to appreciate.

>This is a wave
> cancellation process that causes all energy flow in the rearward direction

> energy flow is occurring. This is very similar to mulipath fading where
> multiple waves combine at the single point in space to a net wave of 0
> energy. You cannot measure a total signal yet the energy associated with
> each component still exists.

This concept is pure hogwash. If energy exists it can be measured--if none is measured it doesn't exist. If multiple waves exist in space and the net energy in the wave is zero in one direction, it is greater in another direction. This is the principle of obtaining gain in directional antennas.

>The law of conservation of energy is not violated by the process of wave
> cancellation. Total energy dissipation is equal to total energy
delivered -

There is no energy dissipation in reflection from a lossless discontinuity, the above statement is untrue.;
>

Steve, we have already discussed this item ad nauseam during the past several weeks with no agreement, so I see no need to discuss it further, because there is no way I'm going to agree with your position. I suggest you review the action of electromagnetic waves on arrival at a medium that causes total reflection to determine the correct relationship between the voltage and current at the reflection point. You will discover that both voltage and current cannot go to zero simultaneously, and the the energy in the waves cannot disappear during the wave cancellation.

> > The crucial point to remember concerning reflection and re-reflection is

This is all well and good and can be proven by TV ghosting. But your response
didn't address what happens at a Z0-match. Can we add modulation to a signal
to "see" what happens at a Z0-match? I suspect we will indeed see a re-reflection
of ghosts on a TV screen.

604. NBS Conjugate Match & Z0 Match Definitions

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-07 00:00:00 UTC
From: Richard Clark <rwclark@rwclark.seanet.com>
Message-ID: <sEHfOap4wudSdUxQ6wo+EolxtNQm@4ax.com>
Source record: 178234

Hi All,

It has been a quagmire with the Matching threads and Virtual Short threads. And the lung volume on some of these with initial postings running 200+ lines? I get the impression of the speaker wanting to explain the theory of wave mechanics in one breath. And trying to get in, edgewise? Which side issue? This shotgun style shatters any simple approach.

I don't need a fractal generator when my news reader, Agent, can show me a random tree construction (we're stuck in a fractal folks!). So in the grand tradition of the internet I present my own Opus.

During my tenure in Metrology, the standard text on the subjects Conjugate Match and Z0 Match were formalized. Insofar as your access to the NBS standard methods, these definitions may be found in "Microwave Theory and Applications," Stephen F. Adam; or they may be found in Hewlett-Packard's Application Note 56, or they may be found in the original works by R. W. Beatty published in IEEE Transactions in the early 60's.

The following terms are those understood by Metrologists at NBS and Primary/Secondary Standards Labs:

Substitution Loss:
A general term referring to the change in power absorbed by a load when first one waveguide junction (these words are used in the broadest sense) and then another (such as an attenuator) is used to connect a source to the load.

Transducer Loss:
What the substitution loss becomes when the first waveguide junction is a perfect transducer and initially the maximum available power is delivered to the load.

Insertion Loss:
What the substitution loss becomes when the first waveguide junction is a perfect (lossless and phase-shift-less) connector, so that in general there is some initial mismatch loss.

Attenuation:
What any of the above losses become when the source and load both have Z0 impedance. Under these conditions, what is measured on an attenuator is a property of the attenuator alone, so that this is the ideal system in which to make measurements.

Residual Attenuation:
The minimum attenuations of a variable attenuator. What is measured when a variable attenuator is set to it minimum position and inserted into an ideal system.

Incremental Attenuation:
The change in attenuation between minimum setting and any other setting on a variable attenuator. Residual Attenuation and Incremental Attenuation together make up Attenuation.

Conjugate Match:
The condition for maximum power absorption by a load, in which the impedance seen looking toward the load at a point in a transmission line is the complex conjugate of that seen looking toward the source.

Conjugate Mismatch:
The condition in the situation above in which the load impedance is not the conjugate of the source impedance.

Conjugate Mismatch Loss:
The loss resulting from conjugate mismatch.

Z0 Match:
The condition in which the impedance seen looking into a transmission line is equal to the characteristic impedance of the line.

Z0 Mismatch:
The condition in which the impedance seen looking into a transmission line is not equal to the transmission line characteristic impedance Z0. In general, conjugate match is a case of Z0 mismatch.

Z0 Mismatch Loss:
The loss resulting from a Z0 mismatch.

Conjugate Available Power:
Maximum available power.

Z0 Available Power:
The power a source will deliver to a Z0 load.

Walter:

The *only* point of physical wave reflections in the example that you
presented is at the open circuit terminating the 1/4 WL stub.

Why do you make statements like this? Why can't we disagree and stick to
the technical points? I disagree with some of your arguments but I would
never tell you to go take a refresher course. This is unnecessarily
insulting.

If you are correct and I am wrong, then you should be willing to discuss the
details of an example on this NG. So far in this thread your arguments
against me have been "I'm right and Steve is wrong". Let's pick a specific
example, define all conditions and then discuss the steady state power flow,
reflections and the conservation of energy. Pick a situation where an
impedance match occurs through a 1/4 WL transformer or a shunt stub. What
do you have to lose?

There are firm standards that can be viewed at:

http://www.dscc.dla.mil/Programs/MilSpec/ListDocs.asp?BasicDoc=MIL-C-17

and downloading the desired document. In many cases, the specifications are inactive for new design, however, manufacturers who comply with these standards all deliver products that walk, talk, and look the same.

Of course the operative word is "comply." Radio Shack does not comply, nor do most suppliers to the ham radio market. There are two reasons for this: 1) cost, 2) most hams don't know the difference.

Personally I try to use Andrew Heliax wherever possible and "real" RG-213 for flex pigtails. Flea markets are a good source of Heliax and I will buy short 'unusable' pieces that have connectors, just for the connectors.

>That said, the best value for the money right now are the Times

Speaking of TImes Microwave, they don't feel that RG numbering is dead, in fact try:

http://www.timesmicrowave.com/products/military/TL14/TL14.htm

and you can download page 30 and find RG-213 at the bottom of the page.

I realized that I did not write what I wanted to say. The above statement
should have read as follows:

The *only* point of *total* physical wave reflection in the example that you
presented is at the open circuit terminating the 1/4 WL stub.

There are partial wave reflections and re-reflections occurring at the
impedance junction where the stub is connected.

Wave reflection only occurs at impedance discontinuities resulting
from changes in the physical characteristics of the transmission line
'seen' by the traveling wave. Opens and shorts are examples of such
discontinuities as are changes in Zo, or the insertion of shunt or
series impedances.

Interference fringes themselves do not cause reflections unless the
media is nonlinear in which case it is still the change in
transmission line characteristic impedance which causes reflection.

> Are you then also saying that no
> reflections can occur as a result of wave interference?

Absolutely correct.

Why not just use a dipole? You will need a tuner to use a longwire. MK

612. Adjust swr on beam?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-07 00:00:00 UTC
From: David <k4zzrNONSPAM@gate.net>
Message-ID: <8rnmer$1a8s$1@news.gate.net>
Source record: 178242

The SWR on my Hy-Gain Th5Mk2 antenna is a bit high in the area of the 20mtr band where I operate the most. It's center resonant (1:1) frequency is 14.230 and it scoots up to about 3:1 at the high end of the band. It's under 2:1 all the way down into the CW portion but I don't operate down there so I'd like to move the center freq up about 60khz. In other words I want under 2:1 swr from 14.350 to 14.175.

I don't have a noise bridge or swr analyzer so it's going to be a "best guess" adjustment. So, folks, please give me some advice. Would you suggest shortening all of the radials about an inch? This is a dual driven beam, so would I shorten the ends of each element the same amount (an inch)? Would I also shorten the reflector and director? Since this is a trap tribander I would assume shortening the outer ends of each element really wouldn't affect 10 or 15mtrs, would it?

Thanks in advance for your suggestions,

David,K4ZZR

Gary,
I've never had any luck with a long wire antenna, so I'd
recommend using a dipole. But, there are plenty of people
who do use, and like a long wire (or random wire) antenna.
Your going to need a good ground system for the 'other half'
of your long wire antenna, and probably a tuner of some kind,
if you plan to use it on more than one band. For a long wire
the 'best' length is as long as possible, and as high as possible.
You just have to work with the room that you have.
Good luck...
'Doc

Bart, given the following, what would be the power in the first ghost
relative to the original signal assuming lossless T-lines?

300 ohm 300 ohm
TV generator---300 ohm line--+--1/2WL 51.5 ohm coax--+--TV receiver

I think I have one involving TV signals and lossless feedlines.

300 ohm 300 ohm
TV generator---300 ohm line---+---1/2WL 51.5 ohm coax---+--TV Receiver

Notice the simularities to my previous example with the Z0s simply
reversed. P+ = Pg + P- and P- = 1/2P+ So the power reaching the
TV receiver is the same as the reflected power and half the power
associated with a particular video object is accepted by the TV
receiver and half is rejected in reflected power. If all the reflected
power is re-reflected at the Z0-match, the power in the object's first
ghost will be 1/2 of the power in the object's original signal. If
there is only 50% re-reflection at the Z0-match that power will instead
be 1/4 the power level of the original object. It should be easy to prove
and measure one way or another.

The beauty of a random wire antenna is that it doesn't have to be any specific
length. The only things that matter are as high and long as possible and it'll
operate on any MF/HF freq., one wire = all nine MF/HF ham bands.
>
You'll need a tuner like the MFJ 969 or 941E to get the wire feedpoint
impedance converted to 50 ohms and you should also string a counterpoise wire
on or near the ground which can also be of random length. I've done several of
these over the years, ya can't beat the bang for the buck.

Hi -

I hope that there won't be any problem about asking an antenna question here. Lately, I have begun to wonder.

I've been looking at the St. Louis Vertical for a low profile, easily hidden antenna to use on a tiny lot in a mobile home park. The original design used TV twinlead radials. Apparently there is a newer radial design using flat TV rotator cable radials, but I can't seem to find a description of them. Can anyone help me?

Thanks and 73, CJ K0CJ

>
> Bill W0IYH
>
Fine Bill, but this concept doesn't negate the example in my Mar/Apr 1998 QEX article, where the hardware short is a 150-ohm resistive load on a 50-ohm line, with the partial transmission and partial reflection with reflection coefficient of 0.5. In this example the reflection coefficients of voltage and current from the load mismatch are amplitude 0.5 at angles -60 and + 120 respectively, while the coefficients of the stub mismatch are 0.5 at angles +60 and -120 respectively. The resultant voltage angle is 0 degrees and the resultant current angle is 180 degrees, establishing a virtual open circuit that re-reflects the energy contained in the two sets of reflected waves. Since the partial short provided by the 150-ohm terminating load determines the amplitude and angles of the inerfering reflected waves with resultants that establish the open circuit, would not this satisfy the requirement that a virtual open or short requires a hard short for its origination?

Richard, this application note is Ref # 120 in my Reflections, from which I based my statements in my early QST series in the 1970's, and in the book.

>or they may be found in the
> original works by R. W. Beatty published in IEEE Transactions in the early
>60's.

My Ref #121 in Reflections is: "R.W.Beatty, "Intrinsic Attenuation,: IEEE Transactions on Microwave Theory and Techniques, V ol MTT-11, no. 3, May 1963, p 179.

These data have been the basis for all my screeching and yelling from the beginning, even before the controversy began. According to Beatty's "Intrinsic Attenuation", there is a conjugate match whenever all of the available power from the source or network is being delivered to its load. I've been told by the various 'experts' that this is not true. I just can't seem to win.

Walter, I am not going to get involved in trying to refute or resolve every mind-twisting argument that has ever been made about wave mechanics.

My input that is at the top of this article is absolutely the bottom line for me. The basic principles that are involved are as crystal clear for me as anything I have ever seen in my entire life.

I just can't believe that this goes on and on and on, year after year after year. I keep asking myself "what is the real game, the real agenda, the real payoff for this ridiculous haggling over this ridiculous subject?"

This topic has a life of its own that is never, I mean never, going to be *permitted* to go away. If anything *should* go away, this is it.

Hi George--

I remember those days--Jim Hartley, W1DIS modified his Johnson Desktop for "ultra-modulation". The wattmeter (and my S-meter) would indicate upward modulation, but the signal didn't splatter because the negative peaks never quite reached cut off. I believe Jim used a Panadapter rather than a meter to monitor his waveform.

I want to re-run some tests with my solid-state AM rigs to re-evaluate what happens at 100% modulation. As I recall, when I tuned the PA and driver of these rigs for minimum power output fluctuation under full modulation, this correlated very closely with achieving a 2:1 carrier-to-peak voltage ratio when viewing the envelope on the scope. The presence of upward or downward modulation correlated with either negative peak clipping or a carrier-to-peak ratio of less than 2:1 on modulation peaks.

Hi Walt,

From the references already cited:
"BASIS OF ANALYSIS
To analyze a particular case of mismatch an appropriate basis of calculation must
be chosen. If the power actually delivered to the load is to be compared with maximum
available from the source, this is on a conjugate basis. If comparison is made with the

power the source will deliver to a Z0 load, this is on a Z0 basis. These are two of a number of possibilities."

Through every discussion to date, I have seen both basis of calculation being intermingled by many correspondents here.

What Basis of calculation do you use, Walt?

Exclusively, or a varying Basis with respect to the scenario? Steve, you can chime in too. Have you guys got your Basis crossed?

> now !!! Thanks,

Hummm, thats a definate contrast of opinions thats for sure. For my 2
cents worth, I think not grounding the antenna a bad idea from a
lightning standpoint. And I don't really think it matters a whole heck
of a lot whether it's grounded or not as far as chances of being hit.
How well the antenna streams will have more of an effect. Face it, the
antenna will act as a lightning rod no matter if grounded or not. It's
much better to make an easy path to ground for the eventual strike
rather than let the lightning decide where it wants to go. If the
antenna is rugged enough and you have a good low resistance ground, you
can take a direct strike with minimal damage to anything. If the antenna
is not grounded, you have a high resistance and the antenna will melt
like a piece of solder, and blow out anything in it's path to ground.
"Which it will choose, not you".
Much better for you to choose. As far as grounding the rig, thats really
up to you in my opinion. If the rig is tube type or runs off line
voltage in any way, it should at least be grounded to a power plug
ground pin.
If the rig is low voltage 12v etc, it really doesn't need a ground at
all. Unless you just want one. As long as the antenna and feedline is
proper there is no real need for an rf ground in the shack. A complete
antenna such as a dipole needs no rf ground at all. A vertical needs the
rf ground below the antenna. Having an rf ground at the shack is kinda
silly, unless the antenna leads all the way to the radio. And I'd never
really want to do that unless no other way. I can't think of why gap
would advise against lightning suppression, and no grounding. I don't

think thats very good advice, and could end up causing some real damage someday, somewhere.
I guess they think that being most will be ground mounted, the bulk of the strikes will follow the antenna to ground, which is probably true, but you can still have plenty of energy going to the house from the antenna. Poof, goes the rig. And if the ground return from the antenna to ground is really poor, it could be "poof" goes part of the house if the strike follows that path to ground. MK

If it was a single-bander all you'd have to do is move the ends of the elements inward about a quarter inch each. But it's not a single-bander, it's a very complex contraption I wouldn't touch, not even with an anlalyzer because of the probable interactions on the other bands unless I knew exactly how the thing works. I'd call Hy-Gain and get it straight from them. I'll take a flyer and bet they'll tell you it meets it's specs and to leave it alone and put a tuner in the line.

The answer is in the question. . .

Just what are you intending to ground?

The GAP is a vertical dipole - center fed. You wouldn't dream of grounding the business end of your horizontal dipole so you shouldn't be thinking about grounding this dipole either.

Now - are you talking about grounding the mounting mast? If you are on the roof, you have just added a vertical wire that is a great source to couple with the antenna or detune it and cause all sorts of grief.

When I first got my GAP, I ran a wire from the mast on the roof to a ground rod. I had terrible RF in the shack. It was so bad it would shut off the power on my XCVR. Georgeat GAP told me to get rid of the ground wire and run my feedline straight down for as far as I could before going horizontal with it. That cured the problem. He suggested taping about a foot of the coax to the groundng rod before it takes a right angle turn to the shack. Theory being that lightening likes a straight path and will jump to the ground rod before it turns and goes back to the shack. I don't know how sound that theory is but I do know getting rid of the ground wire cured my RF blues.

in
> the two sets of reflected waves.

In the case where a shunt stub is used to match a 150 ohm load, the total rearward traveling voltage at the stub connection point goes to 0 V. The total rearward traveling current at this point simultaneously goes to 0 A. This is rearward wave cancellation such that no net rearward power flow occurs forward of the stub connection point. A total re-reflection of the reflected wave simply does not occur, in fact, it is physical impossible under the conditions that you describe.

>Since the partial short provided by the
> 150-ohm terminating load determines the amplitude and angles of the
> inerfering reflected waves with resultants that establish the open
circuit,
> would not this satisfy the requirement that a virtual open or short
requires
> a hard short for its origination?
>
> Walt W2DU
>

In the example that you describe above, the forward source wave arriving at the stub connection point sees a physical reflection coefficient equal to -0.333. As a result of this physical reflection coefficient, there is a reflected source wave created in the main transmission line line. The steady state impedance match occurs because the steady state reflections from the antenna and the steady state reflections from the stub termination both deliver a rearward traveling wave back into the main transmission line. The net sum of these two steady state rearward traveling waves combine to cancel the source reflection created at the stub junction. The net rearward traveling ave goes to 0 V and 0 A. This wave cancellation process

is all that is necessary to explain the impedance match. A virtual short circuit simply does not exist.

If you define the example conditions, I would be happy to discuss this in more detail.

I think you should try using one of those MFJ Artificial Grounds. You run another shorter random length wire as a ground and the device tunes it to act as an effective counterpoise.

MFJ makes a combo antenna tuner and artificial ground that is perfect for random wire antennas. I just happen to have one in perfect condition (my antenna plans changed and I never used it) I will sell it for $100 plus shipping.

>I want to re-run some tests with my solid-state AM rigs to re-evaluate what happens at 100% modulation.<

To answer myself, here's what I found. With the 6-meter Nor'easter set for 3.0 watts output and tuned as perfectly for 100% modulation as I could get it, my Welz 220 (and a Bird 43) didn't budge regardless of modulation percentage. However, my Bird 4391 told a different story. The manual says my 4391 doesn't indicate average (heating) power in CW mode, but mine seems to because I saw a power increase to approximately 4.3 watts output under full modulation. Moreover, it correctly indicated 12.2 watts PEP under 100% modulation.

So, don't look for your Bird 43 to change, but more sophisticated instruments such as BC modulation indicators and the Bird 4391 will.

And that's the name of that tune.

Suggestion - use the Beverage wire and a ground return to
operate a relay to switch the terminating resistor on or
off. You will then have the best of both worlds.

Reg.

640. Relay replaces Trap

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-07 00:00:00 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <8rms8mgbm1@uranium.btinternet.com>
Source record: 178306

Suggestion -

To shorten an antenna to resonate at a higher frequency,
insert a relay in the wire where a trap would normally be
used. The antenna conductor up to the relay can be twin 20
awg speaker wire or something similar. Operate the relay
from the shack to connect the length of conductor beyond it.

In the past I have used a reed relay at 100 watts RF. Would
need a vacuum relay for high power.

Anybody else done this to save loss in a trap ?

Reg, G4FGQ

It goes back a long way further than that. Sometime back in the 1960s
(or maybe even earlier) G3IMX devised a quad element for 14MHz that was
the size of a 21MHz element. The loading was capacitive at the high-
impedance points.

Imagine a square element, fed at the bottom. The two loading wires that
bring the resonance down to 14MHz run parallel to each vertical leg of
the loop, inside the loop. At each side, a short jumper wire connects
the mid-points of the two vertical wires. The lengths of the two loading
wires adjust the resonance.

G3IMX's clever trick was to insert a 21MHz trap in the jumper wires, to
make a true dual-band element. The loop was self-resonant on 21MHz, and
the loading kicked in on 14MHz. A full-size 10m element could then be
nested inside. This idea was patented, and maybe G3IMX sold plans or
parts, but as far as I know it was never published in a magazine.

We will be building a 20 m vertical to go up on the roof of our 3 story apartment building. We will be mounting the antenna on a vent pipe up on the roof. We were wondering if attaching the shield of the coax to the vent pipe would provide efficient enough counterpoise? Or would we still need to lay out radials?
Please email me direct at: N9YLN@aol.com

Renee,

I'd say try it! What have you got to loose? I'd put a choke at the feed point (5-6 turns of coax) and run the coax away from the antenna at 90 degrees. If it doesn't work, no QSOs, then add a few radials, 3 should do.

Hi Reg,
You didn't mention how you operate the relay from the shack, assume you run relay DC current thru rf chokes to 2 speaker conductors. Novel idea, may give it a try.

I have given up on trying to find the motorcycle fork cover suggested to cover the coil on my screwdriver antenna. I have contacted 6 motorcycle shops and no one has ever heard of the maker or model, Daystar model 69. While at a hamfest last week I walked around the parking lot and saw that just about every screwdriver antenna there had heavy wall clear plastic tubing with a flat, evidently machined, top under the stinger mount. It looks like mine would require 2.25 ID and I would like to acquire enough to build three covers. I need one for my DK3Z, one for my N9JMX Allbander and one for a spare. Top piece is about 3/8 inch thick and machined to fit the 2.25 ID tubing. The cover for the Allbander is approx. 2 foot long, not sure on the DK3Z at this point
Where can you find the tubing and top piece?

I've done a similiar thing for 20m/17m operation. The quad reflector element is sized such that a fixed open-wire stub can be either shorted or opened by a relay. Open it's capacitive and resonates on 17m and shorted it's inductive and resonates on 20m. The driven element is simply fed with open-wire feedline on both 17m or 20m. The result is a dual band quad beam.

VE9SRB wrote:
> A refection of the forward traveling waves does not
> occur as a result of this forward wave cancellation.

But it resembles a reflection. You said voltages go to zero at a virtual short. The voltages in those two forward traveling waves have cancelled each other out, i.e. gone to zero at the Z0-match point. The two powers associated with the cancelled energy waves have gone to zero at the Z0-match.

The destructive interference pattern has caused reflected energy on one side of the Z0-match to disappear and appear on the other side of the Z0-match as constructive interference. That displaced energy changes directions much as happens with non-glare glass. It certainly seems to resemble a reflection.

. . . OOPS! 'Nother whole dimension of concerns and you're absolutely correct. The Rohn stuff needs to be based in concrete and that's precisely when the building inspector and the zoning commission goobers get involved. My experience indicates that if you don't do any concrete you can pretty much do as you please within reasonable limits. If your local power company doesn't need building permits to put their poles in the ground without concrete or permits, which they don't, so do you.

Vince,

RG numbering is very dead. There are simply no firm standards for these RG numbers and, hence, no guarantee that the RG213 you have will be the same as another brand.
That said, the best value for the money right now are the Times Microwave LMR series. These are 100% shielded, semi-rigid and proven cables. Sure, you will need to source different connectors, but 3rd party ones are now available for the common LMR240,400 & 600 sizes. The exception is LMR195 which will take all the regular RG58 connectors. Another consideration is a hard-line style of cable - but this will be much more expensive.

Yeah, I really like this antenna. It is rugged and works very well across
the entire 6m band. It has a very good front to back ratio and minimal
sidelobes on 6m. Note, however, that while it loads fine on 2m, the
2m pattern isn't very clean. The elements are roughly 3/2 wave on 2m,
so it has large sidelobes. KMA does make other LPs that have clean
2m patterns. This one is usable on 2m, but it isn't much of a beam on
2m.

TFT makes one with both positive and negative peak flashers that
work simultaneously. It also allows you to set the peak limits separately.
We're allowed to run up to 125% positive modulation, but only 100%
negative modulation (for obvious reasons), so we need to be able to
set different positive and negative peak limits.

Gary, remember all the debates, etc. re "Super Modulation" and "Extended Positive Peak Modulation?" A lot of that was the vogue prior to WWII. The old "Radio" magazine - forerunner of CW - ran a series of technical articles in 1939 or 40 as I recall. They were highly in favor of the technique as a means for improving AM efficiency without increasing bandwidth significantly.

I can recall when all conscientious AM operators - especially the high-power boys - had carrier shift meters and peak modulation detectors in the shack as standard operating equipment.

My, how times have changed . . .

Rick,

Brilliant!
If I connect a motor to the plumbers snake so I can crank
from inside the shack, will I be violating any patents? Will
I be in danger of being sued? And the biggest question of
all --- was it *really* Al Gore who invented fractal antennas?

Exactly. He has to go inside the range. As was shown, the ferrites
on the heavy wiring are not a safety hazard. BUT - he has to know
what he is doing to apply them. You can't choke the power cord
with Radio Shack clamp on chokes, as was recommended prior
to my first post. It is too big. It is also of doubtful benefit. He can't
get "regular" (ie not the clamp on kind) toroids on the power
cord without dissassembling the cord from the range. Much
smaller chokes can be applied to the low voltage DC supply lines
and the signal lines, where they are likely to do more good. Your
comment about safety earlier referred to the heavy wires, which
I told him to avoid.

Walter presented a simple example where the input impedance or the effective line impedance at the input of a 1/4 WL stub line terminated in an open circuit is a short circuit. Walter defined this short circuit as a "virtual short circuit". I don't think anyone would disagree with the fact that the input impedance to this stub line is a short circuit. I would also not disagree with Walter calling this type of a short circuit a "virtual short circuit".

However, it is very important that everyone reading this thread understand that this is not the "virtual short circuit" that Walter and I disagree on. The definition of the virtual short circuit that I disagree with is related to impedance matching in the transmission line. In this case, Walter says that when an impedance match occurs, a virtual short circuit is created at the match point for only the reflected waves such that a total re-reflection of only the reflected waves occurs.

Short Circuits on a transmission line:

There are basically two types of short circuits that can occur in a transmission line. Before considering them, let's review some fundamental basics.

In any transmission line, the forward or rearward traveling waves only see the characteristic impedance (ZO) of the transmission line in which they travel. At all times, the following relationships remain valid:

Vforward / Iforward = ZO and Vrearward / Irearward = ZO

At any point in the transmission line, the total voltage is equal to Vtotal = Vforward + Vrearward. A short circuit will occur at any point on the transmission line where Vforward and Vrearward are 180 degrees out of phase. In this case, Vtotal = 0 V and the effective line impedance at this point is equal to 0 ohms. It is very important to understand that the effective line impedance in a transmission line is not a physical mechanism for wave transmission or wave reflection. Wave reflections will only occur at physical impedance discontinuities in the transmission line.

In any transmission line where two forward traveling waves are 180 degrees out of phase, the forward traveling voltages are 180 degrees out of phase and the forward traveling currents are 180 degrees out of phase. In this case, the two forward traveling waves cancel each other and the net forward traveling wave is 0. A refection of the forward traveling waves does not occur as a result of this forward wave cancellation. The same discussion holds true for two rearward traveling waves 180 degrees out of phase.

The other point to mention is that at any physical impedance discontinuity, the level of reflected voltage created at the discontinuity is equal to the incident voltage multiplied by the reflection coefficient. The level of voltage transmitted to or through the junction is equal to the incident voltage plus the reflected voltage.

Now back to the short circuits. The first short circuit in a transmission line is the obvious case of a physical short circuit terminating a transmission line. At this physical short circuit, the reflection coefficient is equal to -1 and the reflected voltage is 180 degrees out of phase with the incident voltage. The total voltage at the short circuit is 0 V and a physical total reflection of voltage, current and power occurs.

The second type of short circuit that occurs is where the effective steady state line impedance at some point along the line is a short circuit but a physical short circuit does not exist at that point. For example, 1/2 WL away from a physical short circuit terminating a transmission line, the effective line impedance is a short circuit. In this case, the forward and rearward voltages are 180 degrees out of phase and the total voltage at that point is 0 V. It is also critically important to understand that the forward and rearward traveling waves do not see this short circuit line

impedance as they travel through this point. The forward and rearward waves only see ZO as they travel through this point. No wave reflection occurs at this point, only at the physical short circuit terminating the transmission line.

In the example presented by Walter, a 1/4 WL open circuit stub was connected in parallel with a transmission line terminated in ZO. At this connection point (junction), the effective line impedance is a short circuit. In this context, I would not disagree with calling this a "virtual short circuit". Again, this is not a situation where an impedance match is created.

What is physically happening at this junction point is quite complex and cannot be fully appreciated by looking at only the steady state conditions. The real question here is the following: Is the voltage and current arriving at this junction *physically* reflected back towards the source? It is an absolute fact that not *net* power is delivered to or through the junction. However, although there appears to be a "virtual" reflection of voltage and current at the junction, a physical reflection of voltage and current is not occurring at the junction. To believe this, we must realize that there is forward and rearward power flow occurring in the 1/4 WL stub. So, if a total reflection of power were occurring at the junction how could be real power be traveling in the stub line? Note that no net power is delivered to the stub line.

What happens in this transmission line system is the following (this will help us understand what happens when we discuss an example with an impedance match):

The forward source voltage of +1 V arrives at the junction point. The physical impedance discontinuity it sees at the junction is the parallel connection of the transmission line connected to the antenna and the stub line. The impedance it sees is the characteristic impedances of the two lines connected in parallel. The physical reflection coefficient at the junction is -0.33. As a result, a reflected voltage of -0.33 V is created. This -0.33 V travels rearward towards the source. The total voltage at the junction is now equal to +0.66 V (+1 + -0.33). This +0.66 V is delivered as a forward traveling voltage into the line connected to the antenna and into the stub line.

Let's look at what happens to the +0.66 V delivered into the stub line. This voltage travels 1/4 WL to the open circuit termination, it is reflected and travels rearward back towards the junction. The rearward voltage arriving back at the junction is now -0.66 V. The reflection coefficient this rearward voltage "sees" at the junction point is also -0.33. As a result, a re-reflected voltage is created in the stub line. The total voltage created at the junction from the reflection in the stub line is delivered as a rearward traveling voltage in the main line and a forward traveling voltage in the line connecting the antenna. This wave reflection process in the stub line continues until the steady state condition is reached.

In the steady state, the total reflected voltage in the stub line arriving back at the junction is -1.0 V. Seeing a reflection coefficient of -0.33, the steady state re-reflected voltage is +0.33. The total voltage developed at the junction from this reflection is therefore -0.66 V (-1 + 0.33). This -0.66 V is delivered as a rearward voltage in the main line towards the source and adds to the initial voltage reflected at the junction (-0.33 V). This -0.66 V is also delivered as a forward voltage towards the antenna and adds to the initial forward voltage delivered towards the antenna (+0.66 V). The total steady state rearward voltage traveling towards the source is now -1 V (-0.33 + -0.66) and the total steady state forward voltage in the antenna line is 0 V (+0.66 + -0.66).

The cancellation of forward voltages in the line connecting the antenna does not violate the principles of energy conservation. Conservation of energy demands that the total power delivered into the junction be equal to the total power "exiting" the junction, assuming no power dissipation occurs at the junction. In this case, the source "delivers" 1 W of power to the junction with 0.11 watt reflected (0.33^2 / Zo) and 0.44 W (0.66^2 / ZO)delivered forward into both the antenna line and the stub line. The reflected power arriving at the junction from the stub line is also 1 W. The re-reflected power in the stub line is equal to 0.11 W (0.33^2 / ZO), the rearward power delivered into the main line is 0.44 W and the forward power delivered into the antenna line is also 0.44 W. The forward powers traveling in the antenna line are 180 degrees out of phase so a complete power cancellation occurs. The rearward powers in the main line are in phase and add to a total rearward power of 1 W.

It's late, if this is not clear, please ask any questions you would like.

>

When two waves are traveling in the same direction in a transmission line, if the total voltage of the wave traveling in that direction goes to 0, then the total current traveling in that direction must go to 0 as well. A traveling wave cannot have 0 voltage with some current nor can it have 0 current with some voltage. Voltage and current in a traveling wave cannot exist independently of each other. Note that we are not discussing the situation where total voltage in the transmission line goes to 0 - IE. Vforward + Vrearward = 0.

In the particular case of impedance matching, a situation occurs where two (multiple) waves traveling in the rearward direction combine to a net rearward traveling wave of 0 voltage and 0 current. This is a wave cancellation process that causes all energy flow in the rearward direction to cease. The individual wave energy still exists but no net or total energy flow is occurring. This is very similar to mulipath fading where multiple waves combine at the single point in space to a net wave of 0 energy. You cannot measure a total signal yet the energy associated with each component still exists.

The law of conservation of energy is not violated by the process of wave cancellation. Total energy dissipation is equal to total energy delivered - 0.

It is physically impossible for a traveling wave to have current while having 0 voltage. It is also physically impossible for a traveling wave to have voltage while having 0 current. No text reference would state this to be possible.

We are discussing wave(s) traveling in a single direction. We are not discussing total voltage or current which is a function of waves traveling in opposite directions. Total voltage can be 0 while total current is not (short circuit line impedance) and total current can be 0 while total voltage is not (open circuit line impedance).

My goal was to have a standard length of coax that I would use when measuring antenna impedance with my Palomar noise bridge. I carefully characterized a section of cable and then began testing various R-jX loads made from w resistors and fixed caps. I then used ZL-ZIN (nice program BTW) and compared its output with the impedance of the actual load.

Results compare pretty well as long as the SWR at the load is not way high and the test frequency is close (+/- 5%) to the wave length or multiple frequency of the cable. The frequency restriction means it will be difficult to come up with one cable length that works on all bands. Am I doing something wrong? I expected this to work over a wider frequency range. I know I need to avoid test frequencies close to odd multiples of the wave freq. Thanks in advance. 73
Jerry, W0PWE

```
Here are my cable parameters:
Type = Belden RG-58/U
Physical length = 60.0 ft
Resonant freq. = 10.675 MHZ
Characteristic Impedance = 52.2
Loss for 60ft @ 10.675MHZ = .82db
Velocity factor = .651

No.

The sun is rearranging the matter that constitutes hydrogen to make helium,
and it is converting a small amount of it into energy. E = mc^2. The
amount of m plus mc^2 does not change.

Care in wording is essential here. To the physicist, the hydrogen is not
"destroyed", as in blinking out of existence. And the helium and energy are
not "created", as in "In the beginning...."

It's not an issue of being anal about the terminology. The two are not the same, and confounding them leads to all kinds of erroneous conclusions.

Power does not move. Power is not conserved. This discussion might be clearer, and arguments that are not-wrong but not-entirely-correct might be avoided by being "anal".

How about "E x H is the energy flux (J/s-m^2), so in fact waves are *defined* by the energy flow ..."?

Source record: 178124

From comments it appears there's some doubt about the inherent ability of a balanced open-wire line to radiate. It is being confused with the radiation which always occurs from a twin line when longitudinal currents exist. But the two effects are unrelated. Even a coaxial line will radiate quite happily when longitudinal currents flow along it.

Cecil gives the correct explanation of radiation from a truly balanced line by stating that although the pair of line currents may be equal and opposite, the two wires do not occupy the same positions in space and so their respective fields do not cancel out at a distance. But he then spoils the story by confusing matters with how near a balanced line can be to other structures before loss (due to effects other than radiation) becomes excessive. That's also unrelated.

Consider a 500-ohm line, wires spaced 4 inches apart, 4 inches long, operating at 1.5 GHz. 4 inches is 1/2-wave at that frequency and we have an excellent radiating system which will still be performing after a fashion over longer lengths on 2 metres.

And a rhombic on 7 MHz is nothing more than a wide-spaced balanced transmission line.

A 1/2-wavelength of transmission line repeats the impedances it sees at its ends. A true 1/2-wavelength of coax (considering the velocity factor and assorted disturbances) can be added or removed from a transmission line with no effect.

I used to do this at VHF using ny Bird wattmeter as part of the 1/2-wavelength of line. Insertion of my wattmeter did not upset the line and removal did not undo any adjustment I may have made.

Bill:

The internal workings of a transmitter is an area where I simply have little experience, so bear with me a bit. I also need to read through some of the posts.

Here's the basic issue for me.

Let's agree that efficiency of a transmitter is defined as the ratio of total RF power output to DC power input. This is not a problem for me. So, from my perspective the total RF power output should include the power lost in the transmitter and the power delivered to the load. Now, when we speak of the "conjugate match" we talk about efficiency in terms of RF power delivered to the load with respect to the total RF power output of the transmitter. I think these are two independent definitions of efficiency.

As an example, could a transmitter be operating in a "conjugate match" at 50% RF efficiency (RF load power/total RF power) but at the same time be operating at a higher efficiency wrt DC input (total RF power/DC power input)?

Steve

Walt:

I don't want to get into any more "I said, you said" discussions, but I seriously would like to understand the semantics of some of your statements.

Above you state that "when loading is adjusted for delivery of all available power .." Do you equate delivery of available power to a conjugate match? I assume that a transmitter will deliver a total power to a load as a function of internal losses and the load impedance. In all cases, I would define the power delivered to the load as the "available power". I don't necessarily equate this to "maximum power" delivery. In your measurements are you adjusting the load impedance to a point where you measure maximum power delivery from the transmitter or do you assume that a ZO match at the transmitter output is the condition of maximum power output?

If I melt down my chain link fence into molten metal, my chain
link fence has ceased to exist. You say, no, it has been converted
to molten metal. I say molten metal is *NOT* a chain link fence.
I also say a helium atom is *NOT* a hydrogen atom.

The only difference between power and energy is time. For most practical
purposes, the flow of time is a constant. The energy flowing past a
point in a unit time is defined as power and the energy is conserved.

When I was in college, Reg, the textbook defined the point at
which the fields cancel for all practical purposes at ten times
the spacing between the wires. This is only loosely associated
with "other structures" which I didn't mention in my posting.

Hi Steve, Walt,

And again, as distinctly shown above, you two seem to be talking your logic based on different Basis of Analysis. As you both persist in posting to this thread which contains

all the necessary definitions, and from an acknowledged authority (at least Walt acknowledges this authority), Why is it that neither of you can flatly state which Basis you employ, and more importantly when?

Physicists refer to what happens when matter and antimatter come
together as "annihilation." My old American Heritage dictionary
defines annihilate as "1. To destroy completely; wipe out; reduce
to nonexistence." In view of this, it's pretty hard for me to
believe that matter is conserved.

Hi Richard, Nick,

Not all resistors are carbon. Plate Resistance is a perfect example of real Resistance in every sense of the word (fully conformable to the odious IEEE dictionary too).

The coupling circuit transforms this value.

The amplifier circuitry establishes this value.

Through the change in drive, bias or feedback, the Plate Resistance follows with its own change. This change is transformed through the coupling to the antenna connector. Looking back into this connector through this change will reveal a Source Z exhibiting a pool of values, any single value dependant on these variables. The pool of values will generally fall within a 2:1 SWR of the nominal 50 Ohms we call Z0. When I speak of SWR here, it is due to the mismatch between the last active element and the antenna port loaded with a Z0 load.

More exotic amplifiers (Calibration Bench equipment - RF Amps limited to 10W) have followers that can force the amplifier to present a known Source Z. These amplifiers are exotic because this costs a LOT of money. The action of these followers (more correctly, the feedback sense path) is to inject an imaginary resistance into the match. In the parlance of design this was called noise gain. I've worked with a lot of Unity Gain precision Amplifiers that were built from 10 dB Amplifiers where the feedback discarded all of the available gain! The 10 dB went to stabilize the Source Z - hence we have a more stable Unity Gain amplifier. A secondary feature of Unity Gain amplifiers is found in Z transformation. The same feedback also maintains the Input Z of the active device controlled by this feedback.

The common amplifiers exhibit this same behavior at a far more modest specification. Where the exotic amplifier discards 10 dB of gain from 10 dB available, the common amplifier discards 1 dB of 10 dB available. Discard means to turn that gain into feedback. The common amplifier's owner expects more than Unity Gain and price drives to the minimum market value in the design. This is why the common amplifiers' measure of Source Z is pooled. Without even that little feedback, the pool would enlarge, the SWR would climb, and the rig would begin to toast at some frequencies. This is the principal

evidence of failure when unbalanced elements (the source of failure) are used in bridged circuits.

This last is compelling proof of the Conjugate Match or the Z0 Match (choose your own poison, but at least declare your preference) and that there is Real Resistance absorbing Real energy entering the antenna connector.

Thus, by design, 1 dB of feedback is employed to actively match against changes of the load within roughly a SWR of 2:1 relative to a Z0 Load. This means that the average amplifier, much less the exotic, does not conform to the idealized Thevenin source (they are non-linear). However for the sake of the argument, such close reading is a slavish devotion. 1 dB feedback is hardly robust, nor does it dominate the over all amplifier characteristics.

This is called Production Engineering. The common design of the average amplifier must compete in the marketplace. This means that the Production Engineer must constrain his design to the most relaxed standards (lowest cost) to solve the technical requirement (increasing cost). 1 dB feed back is a compromise between robbing forward Gain and being tolerant of mismatch. 6 dB would be far better, if you could live with your rig maxing out at 4 dB gain. It also means you could comfortably drive higher SWRs (anachronism: comfortably for more money from a Ham?).

Richard:

I think the basis that I employ in my discussions has been consistent and clearly defined.

As for the conjugate match in impedance matching re: a T-network: I have always stated that a conjugate match will occur at the network output when the source driving the network input delivers maximum power to the load connected at the network output inclusive of network losses and mismatch at the network input.

As for output impedance of a T-network: it is simply defined as the impedance one would see or calculate looking rearward into the network.

As for Walt and I disagreeing, I think that the basis for our disagreement has been stated very clearly. My post to this thread dated Wed October 11, 9:16 AM clearly states the basis of my disagreements with Walter's calculation of output impedance and his definition of the conjugate match re: a lossy T-network circuit.

If anything I have stated seems unclear, I would be happy to address it specifically.

Steve

Very poor conclusion. Most electrical utility companies now refer to themselves as energy companys. They do not charge you for power (watts) they charge you for the energy (watt-hours) that you convert in the appliances in your home. They do that by measuring voltage, current, and time and calculating how much energy was converted in your home. It's easier to do that than to put each of your appliances in an adiabatic chamber along with a calibrated bolometer.

> The only difference between power and energy is time.

Likewise, the only difference between charge and current is time. Seems to be a rather significant difference though.

> For most practical

Humm, dt/dt. Interesting. Once you get your gravity wave detector working, you can plot that. :-)

> The energy flowing past a
> point in a unit time is defined as power and the energy is conserved.

There's probably a difference between a "definition" and an "equality". This argument is a good example of the misuse of the term definition.

Hi Jerry,

I've done this with about a dozen cables around the shack and my binary variable transmission line tuner (coax version of Cecil's method that I built 5 years ago). I took all my leads from Walt's book "Reflections" which is an excellent source for the work you are entering into.

To the matter of your question, Walt's material reveals that for measuring Z, the best choice would be wavelength based and cut to an odd eighth-wave length. This allows for unknown but tolerable loads to be measured away from outrageously transformed values. Mathematically it is casting errors out of the more error prone operations.

Hi Steve,

What Basis of Analysis do you employ?

"BASIS OF ANALYSIS
"To analyze a particular case of mismatch an appropriate basis of calculation must be chosen. If the power actually delivered to the load is to be compared with maximum available from the source, this is on a conjugate basis. If comparison is made with the power the source will deliver to a Z0 load, this is on a Z0 basis. These are two of a number of possibilities.
"Considerable confusion has arisen over the use of terms such as "match" and "mismatch" since it is not always clear just what basis is intended. R.W. Beatty of NBS has proposed a complete set of specific terms and definitions [subject of my other thread, rwc]... From here on, all terms used in this Application Note will follow these definitions where any possibility of ambiguity might otherwise exist. Thus, "conjugate mismatch" and "Z0 mismatch" are used to describe the actual figures obtained in the examples.
"The general formula for power transfer between a source and a load of reflection coefficients GammaG and GammaL is:
((1 - |GammaG|^2) * (1 - |GammaL|^2)) / | 1 - GamaG * GammaL |^2
"where |GammaG| and |GammaL| can be obtained from the SWR's sigmaG and sigmaL by the simple relation:
|Gamma| = (sigma - 1) / (sigma + 1)
This is the fraction of the maximum available power that is actually absorbed by the load. Here the Z0 mismatch losses associated with the source and the load are give by (1 - |GammaG|^2) and (1 - |GammaL|^2) respectively, while the uncertainty in the power transfer is given by (1 ï¿½ |GammaG| * |GammaL|)^2. It can be seen that the rather vague term "mismatch error" applies in general to a combination of calculable mismatch losses and uncertainties."

Yes, time is "the only difference." But Vive la difference! Sometimes,
it's an important distinction. If ignoring the distinction leads you to
conclude that power is conserved, that's a mistake. Power is not conserved.
Energy is.

As for the "power" companies etc., that's an excellent example of how
ignoring the distinction can lead to mistaken conclusions. We/they have
used the terminology loosely for many years. But in fact, they don't charge
for power consumption, they charge for energy consumption. Good thing for
them, because their users don't consume any power at all, but they consume
lots of energy. My bill is based on kilowatt-hours (1 kW-h = 3600
kiloJoules), which is an amount of energy, not power.

Rich

If you don't believe that matter and energy (the combination, since they're interchangeable) are conserved, then you're forsaking one of the most fundamental principles of modern physics. Don't do that on the basis of what the American Heritage dictionary thinks.

Recognize what the definitions in a good dictionary represent. They are an attempt to characterize what a broad range of literate users think the words mean. Sometimes, that does not jibe fully with "extended" meaning employed in technical fields. The one you have provided is a good example of that.

To do justice to the probable interaction of matter and antimatter would require a dissertation in quantum mechanics that Feynman might be able to do briefly, but I can't <g>.

At 10 times the wire spacing the *near field*, which induces
losses into neighbouring structures, may very well be zero
for all practical purposes. In fact its much less than
that. 3 or 4 times is sufficient for most purposes.

But its too late - the *far field* radiation is already
well into its stride.

As for me - I never had any college, old wives' text books
to pass on to the blame. ;o)

Once again, aren't semantics wonderful. Normal language is rather poor
for describing what happens at the quantum level.

Physicists don't define matter in terms of "chain link fences" or "atoms",
nor do they use the American Heritage dictionary to define "annihilation".

You HAVE to look at the math; matter is not conserved, matter and energy
are conserved.

I vote for the Z0-match because - if reflected energy doesn't make it
back to the generator, whether a Z0-match exists or not doesn't depend
on the generator source impedance. I don't see any reason for a ham
to care about a conjugate match except for academic reasons. We can
have a Z0-match without a conjugate match.

One doesn't have to disagree with the matter/energy conservation principle
to believe that an atom with two protons and two electrons is NOT a hydrogen
atom. A hydrogen atom has one proton and one electron and that entity, by
definition, has ceased to exist. Or another way to put it, is a wooden
bookshelf still a tree?

Nope, I don't have to look at the math to know that an atom with one
proton and one electron has ceased to exist and something else has
been created in its place. This is simple binary logic. Either an
atom is a hydrogen atom or it is not a hydrogen atom.

Hi Richard:

I am not really sure of the point of the above discussion.

All discussions that have occurred relative to the transmission line problem, impedance matching and the conjugate match have been based on the generally accepted method used to determine Gamma. In all of these discussions, Gamma is determined as a function of load impedance (or impedance discontinuity) and the ZO of the transmission line. The steady state solution to any transmission line problem can be found using Gamma determined in this manner.

Understanding the differences between an impedance match and a conjugate match is a different issue in my opinion.

In the most general case, ZS, ZO and ZL are complex and of the form R + jX.

The condition of an impedance match will occur when the load impedance ZL is equal to the characteristic impedance ZO. In this case, the forward source power delivered to the transmission line will be delivered to the load and no reflections will exist on the transmission line.

In the general case where ZS, ZO and ZL are complex, an impedance match is not a conjugate match.

A conjugate match occurs when maximum power is delivered to the load. If we define the conjugate match to occur at the source output terminals then, in the general case, more power will be delivered to a load equal to ZS* where reflections exist on the transmission line than will be to a load equal to ZO where no reflections exist on the transmission line.

In the special case where ZO is purely real, when ZS = ZL = ZO, an impedance match and a conjugate match will exist at the same time.

When a lossy tuner is used in impedance matching the discussion is more complicated because we also have to define the point where we want the conjugate match to occur. This was discussed in the previous post that I referred you to.

Feynman says matter and antimatter annihilate one another. Here
is a list of what he says are conserved: momentum;
charge; energy; strangeness. I can't vouch for strangeness,
but the others seem right. Where did you get the idea that
matter is conserved?

Richard P. Feynman was a physicist. According to the Nobel committee, he was a very fine physicist, so good, in fact, that they gave him a prize. When he writes, in his lectures, that if a clock made of matter and one made of antimatter come together they will annihilate one another, who am I to question what he means by the word annihilate? Feynman was usually very careful with his words. If you say that Feynman didn't really mean annihilate when he said annihilate you'll have to prove it if you want anyone to believe you. As for myself, I'm willing to believe that the matter and the antimatter in the clocks is converted to energy, but, once converted, it isn't matter and antimatter any more, it's some other form of energy. Matter is just one form of energy, if Einstein is correct. The energy can be conserved, the form can't.

> total RF power output to DC power input. This is not a problem for me. So,
> from my perspective the total RF power output should include the power lost
> in the transmitter and the power delivered to the load.

Consider a tube amplifier as a simple example:
(A) The DC plate power is the product of DC plate voltage and DC plate current.
(B) The RF plate power is the RF power that is delivered to the plate load resistance (the input resistance of the tank circuit).
(C) A small amount of this is lost in the coil of the tuned circuit (this is the RF power "lost inside the transmitter").

The "plate efficiency" is the RF power that is actually delivered to an external load (B-C) divided by (A). The difference between (A) and (B) is dissipated in the tube itself, not in the "dynamic plate resistance due to internal negative feedback" but in the actual plate dissipation, which is an *entirely different* thing. The plate glows red and gets hot, but the *dynamic plate resistance* does not do *anything* like this. It is a dynamic, internal, lossless feedback mechanism.

> Now, when we speak
> of the "conjugate match" we talk about efficiency in terms of RF power
> delivered to the load with respect to the total RF power output of the
> transmitter. I think these are two independent definitions of efficiency.

No. Conjugate match involves the dynamic plate resistance and the RF load resistance. When the load resistance equals the dynamic output resistance then no more power can be obtained by either increasing or decreasing the load resistance, *while holding everythng else constant*. We see this a lot in small-signal tube/transistor circuits.

BUT, let's be clear about this: This match between load and dynamic resistance has absolutely nothing to do with the definition of efficiency that I mentioned. Specifically, the efficiency of a tube with very high plate resistance (like a pentode) can be identical to the efficiency of a triode with much lower plate resistance, both having the same value of load resistance. Furthermore, the pentode has such a high plate resistance that the possibility of getting a conjugate match is very small. What happens is that if we increase plate load

resistance to try to get a conjugate match, the situation changes. The plate voltage variations become so large that the tube goes into regions where it is no longer acting as a true pentode. Using this shenanigan, we can make the dynamic output resistance look like just about anything we like. We can also get into plate current saturation and cutoff.

Comparing pentodes and triodes, the maximum plate voltage variations and maximum plate current variations are restricted in not exactly, but pretty much the same way.

This dynamic resistance situation is different from the usual passive-network idea of a generator with an actual physical resistor in the generator and an actual physical resistor in the load. In the case that we are discussing, the power dissipated in the generator resistor is 0.0000 watts.

This idea takes some getting used to. All we need to do is imagine a resistor that does not dissipate power. That is the dynamic output resistance of the tube.

Others have talked about "current pulses" in amplifiers, and tried to relate that to output resistance. But a triode (voltage source) and a pentode (current source) can deliver exactly the same current pulses to the same load resistance and yet have drastically different dynamic output resistance. This difference does not prevent equal performance of the two tubes (the triode with low value of plate resistance will need a larger grid drive).

Who said that a field of time-varying E and H vectors derived from
a solution to Maxwell's equations couldn't vary sinusoidally with
distance? I think we've changed topics, however, since the post
I responded to only mentioned "Maxwell's curl equations" in which
sinusoids don't appear (though they may appear in solutions).

So you are saying that the wave equations you are now talking about
don't define waves to travel in the direction E x H? What direction
do they travel in then?

Dennis Ferguson

The curl equations, written in phasor form, contain j-omega.

> So you are saying that the wave equations you are now talking about
> *don't* define waves to travel in the direction E x H?

I certainly did not say that. I said exactly the opposite.

> What direction
> do they travel in then?

E x H is correct. If E is in the plus X direction and H is in the plus Y
direction, the wave travels in the plus Z direction.

Given the NBS definition above, it responds directly to the mutual exclusivity of the two Basis of Analysis for this point; but this is not said by you - or anyone except through indirection. No wonder these threads run 600 postings with some running at 800 line entries.

Steve is having an incredibly difficult time simply stating which Basis is being used, and when; and Walt, who acknowledges this reference, has been completely silent on this point for two years.

There are not that many definitions, they are not terribly written or vague, and yet when two choices are presented, neither correspondent can identify which he employs, and when in his arguments. I am not surprised they are at cross purposes.

Hi Tom,

If we are to lean upon the master, we should also quote him to the matter:

"...conservation of energy. It states that there is a certain quantity, which we call energy, that does not change in the manifold changes which nature undergoes. ...it says that there is a numerical quantity which does not change when something happens. It is not a description of a mechanism, or anything concrete; it is just a strange fact that we can calculate some number and when we finish watch nature go through her tricks and calculated the number again, it is the same. (Something like the bishop on a red square, and after a number of moves - details unknown - it is still on some red square. It is a law of this nature.)"

Hi Cecil,

Energy at a different level is more (or less) energy. To increase (decrease) energy requires the addition (subtraction) of more energy, not a transformation. Energy is not transformed to a greater (lesser) energy. Transformation is, afterall, the change in point of view (reference) of the variables, not a change of the variables themselves.

Hi Richard,
yes, he did say that. Thank you for the quote. Do you think
we could substitute the word "matter" for the word "energy" in that
quote? If we could, I would gladly concede the point to the other
side.

I said it that way because some people equate a Z0-match with a conjugate match. What we normally achieve with an antenna tuner is a Z0-match, not necessarily a conjugate match. Given a transceiver designed to drive a 50 ohm load, a 50 ohm Z0-match is all we need.

> Given the NBS definition above, it responds directly to the mutual exclusivity of the two
> Basis of Analysis for this point; but this is not said by you - or anyone except through
> indirection.

50+j0 looking one direction and 50-j0 looking the other direction is a conjugate match, right? (trivial case) It is also a Z0-match where Z0 = 50 ohms. The analyses may be mutually exclusive but the two *conditions* are not mutually exclusive.

Doesn't allowing for more (or less) energy violate the
conservation of energy principle? Seems to me we have
the same total amount of energy no matter what the level.

The analogy of a switch and tank circuit to a Class C amplifier is a good one and I agree with your conclusion of how this allows greater than 50% efficiency.

But is this supposed to explain the "different kind of resistance that is non-dissipative" that we've been talking about? I don't see where it comes in. Taking the switch and tank illustration to the extreme (ideal) point, let the switch and DC source and tank be ideal (lossless--no arcing, no resistance). Now the efficiency of this rf generator connected to a load will be quite high--100%, I'd guess. But it didn't require any creation of a new kind of resistance to get there--just an rf generator with zero source resistance.

As I understand it, the argument for this non-dissipative resistance goes like this:

1. An optimum match is a conjugate match.
2. A conjugate match is only 50% efficient.
3. We know of rf generators matched to loads with greator than 50% efficiency.
4. But since they have to be conjugately matched (see 1), there must be some kind of non-dissipative resistance at work here to get the >50% efficiency.

I guess I don't agree because I don't agree with (1). Maximum power transfer is not "optimum" if you seek higher than 50% efficiency, so a good, high efficiency match isn't equivalent to a conjugate match. I know this dead horse has been flogged here before, but I've got to get my licks in too.

If you don't give the energy back to the power company in the
form in which you received it then it is "consumed" from their
point of view. If the transformation you cause the energy to
undergo generates entropy then you'll never be able to use that
energy for the same transformation again either, so it is pretty
much "consumed" from your point of view as well. Entropy generation
is energy consumption (at least if I use the "to expend; use up"
dictionary definition rather than the "to destroy totally" one).

> a steel mast than the vee. How much is "not cheap"?

New, about $250 for a 30 footer. As I said, not cheap!
But that's for a *very* sturdy pole.

As for the lightning problem (an this is a high risk area)
I simply plan to disconnect and ground the feedline some
distance before it would enter the house, whenever it is not
in use. I've done that with all my antennas for 50 years.
So far, it's been successful.

Hams used wooden poles for their antennas for many
years in the past, and I haven't heard of any serious
problems as a result. Just use common sense.

731. AM Rod Antenna??

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-22 00:00:00 UTC
From: Wayne Watson <mtn_view@sirius.com>
Message-ID: <39F3D3E2.5CF7707C@sirius.com>
Source record: 178080

On many AM/FM radios there's a rod antenna that collapses. I'm sure it is the FM antenna, and a
small ferrite AM antenna is inside. However, what's the deal with the old AM rod antennas on autos?
Is there actually some sort of ferrite antenna disguised in the fat portion of the rod and the rest
of the rod is used for FM?

Message-ID: <39F3DACF.47A1A4E7@eznec.com>
Source record: 178081

No, the rod functions as both an AM and FM antenna. It's very
inefficient on AM, but that's made up for by a large amount of receiver
gain. The capacitance of the coax acts as part of a voltage divider
which reduces the AM signal from the rod. It's specially made to have as
little capacitance as possible to minimize this attenuation. Someone
with more experience can correct me on this, but I don't think a typical
ferrite rod antenna will receive as much signal as a typical whip of
half meter or so length. If I'm correct about that, a portable AM/FM
radio probably has a ferrite rod antenna mostly because it doubles as
the inductor in a couple of tuned circuits, and it allows use of the
radio on AM without extending the antenna.

Judd

I use a steel scaffolding pole (22') with a one piece windsurf mast on top. There is an extension windsurf mast in the middle giving 43'. The mast is very strong with guys at 120 degrees, I live on Portland on the south coast of the UK which is very windy and have had no problems. Over here we can get the masts very cheaply (free). I just go to a windsurf shop and ask for old ones, these are usually worn out and starting to splinter so a couple of coats of varnish are necessary. They are better than PVC and much stronger. Mine supports one end of a dipole with the other end on the chimney and fed with ladder line.

I've always been a bit nutty abt full-time completely grounded antennas
for my near half-century in the game, to each their own.
>
I had a stack on a well-grounded tower which went thru 100ft. The power
line took a direct strike somewhere in the neighborhood and blew my ham
station all to hell. I was right there, I jumped up on the radio bench and
dove for the equipment plugs and started yanking, it wasn't 30 seconds
later that another strike landed and tossed me halfway across the
basement. So much for the old "lightning never strikes twice" nonsense. We
lost a bunch of appliances, 110vac outlets got embedded in walls on the
other sides of three rooms, etc. Bloody scary stuff. Yeah, I'm paranoid

abt lightning.

George, W5YR wrote:
"So, if anyone has any information on this, I would appreciate hearing from them."

Bird says to consider what + or - 5% accuracy means. Checking the 500 watt scale at a level of 10 watts allows + or - 25 watts variation while the 100 watt full-scale tolerance allows only + or - 5 watts variation.

Bird says that replacing the crystal rectifier should yield + or - 3% of the full-scale reading of the factory calibrated unit.

Bird says inaccuracies may result from spurious signals outside the design range, effects of the deviation from purely sinusoidal wave shape, effects of ambient and instrument temperature, meter movement accuracy, and the history of the instrument`s maintenance.

To calibrate, Bird says, requires concern with the standards used, the media employed, and the operator performing the calibration.

George is surely right. Bird will very likely say, "return it to the factory".

What I'm waiting for is for Gentleman Roy to get a gut full of this crap and hit HIM where it hurts with a SERIOUS suit for libel, slander and damage to his professional reputation among whatever else a good torts attorney can work up from all that has gone on here.
I'd imagine he's harvesting message headers with contents as we speak for submission for his attorney to consider. Maybe Roy will wind up the owner of Fractalcrap, INC and then he can - I started to say he could just burn the building, but I don't think there IS a building. He'll just have settle for burning the company charter. In any case the world would finally be free of fractalcrap.

George, W5YR wrote:
"Can these (Bird slugs) be calibrated in "the field" i.e., my
workbench?"

About 40 years ago I sucessfully recalibrated a Sierra wattmeter which uses the same principle to indicate power, but physically is quite different. It is a big clunker which uses a rotating barrel in place of plug-in elements.

Some years later I saw an article in some ham magazine, I am sorry I don`t remember the details, on how to repair and recalibrate Bird elements.

Return to the factory for recalibration is likely to restore confidence.

Source record: 177930
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.antenna,rec.radio.amateur.misc

This is an email I received from Dan Asbjornsen (kb7uxe) regarding Mike Laferla (k7jml) and his experience with a 10 Meter rig bought from Copper Electronics. The letter is addressed to Jerry Seligman (w7bun) who is very active with the Radio Club of Tacoma.
I thought you may wish to share this information with other hams.
-n7kn

Hi Jerry, my sad story goes like this:

Mike Laferla K7JML purchased an RCI 10M radio from Copper Electronics (mail order)
at a cost of just under $400... Mike had the radio for about 3 months before he installed it and tried
it for the first time... It didn't work. It had cxr on am & fm,but no audio,
and nothing on ssb or cw..
He sent it back to copper for repair or replacement. They returned it saying
it was fixed..
When he tried it again, same thing, no change........ so he sent it back a
second time...
and once again, copper returned it, still not working. once again, Mike contacted copper
they wouldn't return his calls, or answer his e-mails. Mike returned the radio addressed to the
the copper VP.. they returned it, unopened.......
Mike has spent just under $100. in return charges, and still, the radio doesn't work, and it appears
that copper does not wish to face up and deal with the problem.....
Mike has contacted Ranger communications directly, and they have said, THEY
WILL make it right...
(repair or replace ?)...
So the moral of the story,
DO NOT BUY ANYTHING FROM COPPER ELECTRONICS,
THEY WILL NOT SUPPORT WHAT THEY SELL....

And I know for a fact that our radio shop did not go through the whole fleet of radio equipped sedans and test exposure from each one. Yeah, they may have done a paper exam and figured out that there is no danger. But I wonder if they even have that on file. After all, I haven't heard of even so much as an OSHA representative looking for this paper-work.

Aside of the ANSI exposure limits (which already have a fudge factor built in) there is no documented and reproducible "non-thermal" radiation hazard. This whole issue has become a snipe hunt.

Most of the positive studies are so close to the statistical sampling noise floor that even if it is real and even if it does represent a doubling of the supposed "hazard" it is still a very small risk. Other more common hazards dwarf this issue to irrelevancy. And following that wonderfully bogus data by Dr. Liburdy of Stanford University, I really have to wonder if there are any real effects to be found at all.

So we're supposed to do RF studies. I find no fault for wanting to ensure that the RF goes where it's supposed to. Certainly it will reduce TVI and other such problems. Adding test questions and distributing advisories to all hams is not a bad idea. But to keep a study on file so others can subpena this document and make life a legal hell for the ham? What does that accomplish? Does it lessen the RF radiation? Does it make neighbors feel any better?

The writers of this legislation and regulation have every reason to be ashamed of themselves. Not only have they written a fundamentally useless regulation, but they have damaged the credibility of the FCC as a reasonable regulatory agency. This is exactly the sort of fodder anarchists love to use.

It doesn't get any worse than that.

The antenna information is in the public domain. It was published in
73 magazine in the fall of 1999. Dimensions and pictures are there.
I have the magazine. Others have reported that the antenna was
in Comm Quarterly pre-'99. I don't have that publication, but if
what they report is true, then the information went public at least
twice.

Anyone with skill using EZNEC can produce a file from that information.
I have no idea what arrangement you have with the author of that 73
article, if any, or the Comm Quarterly article for that matter, but you are
too late to complain now.

==========
Cecil,

When an SWR meter is connected immediately at the output of a transmitter (it nearly always is) it indicates the SWR on a transmission line which does not exist. Who wants to know that ?

But at least it does correctly indicate the magnitude of the reflection coefficient of the load relative to 50 ohms. Unfortunately it does NOT indicate the angle of the reflection coefficient. So half of the information which might be useful to the station mainenance people is not available.

Reg.

For 6 meter SSB I would reccomend Arrow's 4 element yagi.

It fetures ease of assembly and very good workmanship.

It turns with a light rotator and performs pretty well. I just got one and am quite happy with it.

> OK. The constant K maps one Smith chart to a modified Smith chart.

Yes, and of course Smith charts are commonly printed with "1" in the center, and every point on the chart is then scaled (by the user) by the reference impedance chosen for that chart.

An interesting (well, to me anyway) question that grows out of the original one posted about, "Does a constant |rho| circle on a chart transform on the same chart to a circle if you scale all the impedances represended by that circle by some constant?" That is, "does a circle on one chart (arbitrary diameter and center location) transform to a circle on a chart scaled to a difference reference impedance?" I believe the answer is yes, as a correlary to the original question.

Cheers,
Tom

George, if you peel back the label on the slug you'll find a screwdriver adjustable pot. That will adjust the slug's calibration. But unless you really have the proper setup to do the calibration, I'd send the slug back to Bird. You don't want to twiddle this unless you're 100% absolutely sure that it is the problem.

Tom, of all the many answers to the question, I think yours
is the only one correct.

Only in the case of the generator having an internal
resistance of 50 ohms (ie., a conjugate match) will the
forward power, as indicated on the meter, remain constant as
the load impedance is varied.

The indicated reflected power will of course change with
load impedance.

Again, the SWR meter reacts to voltage and current exactly *as if*
it were installed in a 50 ohm coax line and if one understands
that, length doesn't matter (except for losses). If the SWR meter
is installed between a transmitter designed to drive 50 ohms and
the 50 ohm Z0-match provided by a tuner, all is well. And when we
adjust the SWR to 1:1, we know the exact magnitude and phase of
the reflection coefficient and impedance seen by the transmitter. :-)

My IC-706 delivers full power into a 50 ohm load.
Delivered power falls off on each side of 50 ohms
but forward power does appear to remain constant
until foldback conditions take over.

The programs Ghostview and Ghostscript are used to view and print postscript. They can also convert postscript into a variety of formats, various graphic types and .... pdf

I use this a lot and it works well. On a windows machine select a "printer" of an APPLE LASERWRITER and print to file. Give the file a ps extension. You can then create a postscript file from any windows application. e.g word or netscape.

Using explorer doubleclick on the .ps file, ormanually launch Ghostview and once you see the postscript file in a window, select PRINT, the list of printers within Ghostview includes bmp and png writers, if you scroll down the list you'll see PDFWRITE, tick the box to create a file and you'll end up with a .PDF file.

It takes longer to describe tha to do. Installation of the Ghostview and Ghostscript package is easy now, a single click installs both. The laserwriter printer is on the W95 CD.

Cheers, Ian McCrum, MI5AFL

Are you now claiming credit for creating the file that Roy has on his
site?
From what I understand, these EZNEC files are essentially tables of
numbers. Are the numbers in your "copyrighted" file the same as the
numbers in the file on Roy's site? If not, your copyright would not
apply to that file, and it is not your IP.

: An interesting (well, to me anyway) question that grows out of the
: original one posted about, "Does a constant |rho| circle on a chart
: transform on the same chart to a circle if you scale all the impedances
: represended by that circle by some constant?" That is, "does a circle
: on one chart (arbitrary diameter and center location) transform to a
: circle on a chart scaled to a difference reference impedance?" I
: believe the answer is yes, as a correlary to the original question.

I haven't been reading this thread, so maybe all of this has already
been said. The Smith chart is essentially a plot of the complex
reflection coefficient. The mapping from the complex impedance to the
reflection coefficient or vice versa is what is known as a bilinear
conformal mapping. That is it is a combination of translation, scaling
and inversion. Under each of these a circle remains a circle.
Translation moves all points the same amount, so a circle stays a
circle. Scaling, expands the size of a figure, so circles stay
circles. Inversion is a little trickier. For it you choose a center and
radius a, for the new point you draw a line segment from the center to
the point and call its length r. You then replace the point with a new
one along the same line but at a distance a^2/r. If you start with the
equation of a circle and do this you can readily show that under an
inversion a circle remains a circle too (if the inversion center lies
on the circle, it becomes a circle of infinite radius or a line).

So if I understand Tom's statement correctly, those structures are also
circles, since the above says you can start with any circle on the
Smith Chart, make a bilinear transformation to the impedance plane,
scale the result (or in fact do any translation, scaling or
inversion to an impedance that keeps it a circle on the impedance
plane) and then reverse the bilinear transformation to return to the
Smith chart. All of these transformations map circles to circles.

For the purpose of this discussion, EZNEC is best described as an
intellectual property that you do not own.

Do you still claim to have a copyright on an antenna, as you did above?

So your claim is that it is a violation of copyright to produce a table of numbers which represent the dimensions of an antenna that is in the public domain, and for which radio amateurs and others have been publicly invited to build? Sounds like a weak case to me.

Cecil, you used the word "if" three times.

That would hardly correspond to a positive and determined approach to fault-finding problems in the station mainenance handbook. ;o)

Incidentally, during WW2 the maintenance handbooks which accompanied USA-manufactured radar equipment excelled at describing unambiguously, in a crystal-clear manner, exactly what and how to do things. If you could read and understand English, and were not physically handicapped, you were as good as the radio and electronic engineers at MIT.

Reg.

==========

But that's because the Icom range of HF transceivers (and probably other manufacturers') with a built-in swr meter have an ALC system which is designed precisely to maintain a constant forward power. The swr forward power meter voltage is fed back into the ALC line. (When the reflected power exceeds some pre-determuned level then THAT takes control.)

But that must not be taken to show that the dynamic internal resistance of the IC-706 is 50 ohms. Almost certainly it isn't. What it might be is anybody's guess.

Without ALC, the only condition under which a 50-ohm swr/power meter will indicate a constant forward power versus a variable load is a generator with an internal resistance also of 50 ohms. So with a different internal resistance, depending on how a meter is used or calibrated, it can indicate such things as a reflection coefficient greater than 1.0

Cec, just out of curiosity, how does your IC-706 behave at about 10 or 20 watts output versus changes in load. Just watch forward power while detuning the tuner a long way without touching the transmitter. Make sure the load has an appreciable reactive component.

I promised that I wouldn't respond to any thread that included the "F" word, so this isn't about "F" words, but about a practical side of the lawsuit bullshit.

Whether or not a lunatic holds/doesn't hold, owns/doesn't own, once held/never held any rights to a disputed, copyrighted/not copyrighted 'intellectual' property is specious.

The fact is that when the disputed item is valueless the purloining, theft, misuse, usurpation, copying, misappropriation or defacement of said valueless item does no financial harm to the alleged owner.

No criminal act has occurred. This is a civil (legally speaking only) matter and there certainly wouldn't be any jail time forthcoming, so the only possible (and this is a real stretch) penalty would be the imposition of monetary damages commensurate with the financial loss to the aggrieved party. Since the material is without value there is no financial loss and therefore no damage

I once created an intellectual work when I performed 'original' electrical measurements of a pair of parasitic suppressors as reported on my home page. I declared the material copyrighted to me but stipulated that anyone could freely use the material for non-commercial purposes. Tom Rauch honored that request, Rich Measures did not.

Measures posted the material on his web site, where he was advertising and selling nichrome wire parasitic suppressors. I considered that to be commercial use of my material and politely asked him to remove the material.

He in turn more-or-less told me to go piss up a rope and the material remains, albeit totally twisted (doesn't this sound familiar) into an endorsement of his product. The data of course do not support his claims (familiar territory again) but he has the temerity to claim that they do. He did add, "**Copyright 1997 by W. D. Stewart, Jr" to his web page.

So we have a similar (maybe) situation. I believe I have a (much) better claim of misuse but practically speaking, how have I been financially harmed. Fact is I haven't been and neither has a fruitcake. Whoops, I used an "F" word.

Hypothetically speaking of course.

Sorry.

Wes Stewart

And you worry about RF exposure? Maybe FCC will now establish "Contester Operating Hours" law?
Woman sat in a chair for "whole" 20 hours, we sit for 48 and so far not known case of contester going SK during the contest. Another proof that RF has therapeutic effect and the FCC "RF exposure regulations" are pure bunk!
Is Chipster endangering himself by trying to operate contests?

73 and CU all on 10m with verticals on the beach as N2EE from Cape Hatteras!

Yuri, K3BU

>>A young British woman died minutes after a long-haul flight from Australia when she developed a blood clot.

It has been reported that Emma Christoffersen collapsed and died after sitting in a cramped seat for 20 hours.

The 28-year-old bride-to-be is one of the youngest victims of deep veined thrombosis, which is thought to affect dozens of passengers every year.

The condition, which has been nicknamed "economy class syndrome", struck after the 10,000 mile fight to Heathrow had ended, according to The Sun.

Miss Christoffersen's mother, Ruth, 54, from Newport, South Wales, told the newspaper: "We were told she died from sitting on the jet for such a long time.

"I'd never heard of the condition before but apparently passengers on long flights suffer from reduced circulation and that can cause the blood to clot."

etc.

Hi Jim,

There are no copyright issues with owning/using a copy of EZNEC.

There is also no issue of intellectual property with owning/using a
copy of EZNEC.

Roy is not liable for the use/mis-use of his product (read the legal
fine print in the terms and conditions of its use). Roy does not
warrant what is generated either (except at some additional cost no
doubt ;->).

Some laws to these matters of intellectual property clearly state that
if you do not pursue your rights - you lose your rights. Pursuit over
this matter has lapsed for a period of at least 8 months (Roy, this
was the genesis of your question way back then over just what I had
that was sue-able - the responses were equally silly then). Clearly
this claim against me was abandoned long ago.

And lest we forget - quite a number of fraudulent claims of technology
covered by patents pending were made.... No wonder some arguments are

never returned to again - after the patent office publication revealed those frauds. These may be noted in the record by my refusal to suborn illegal activity in this regard.

Are the frauds actionable? All depends on who took these claims for real (I never did certainly, considering the source; and by all appearances no one else did either).

787. Re: PIRACY BY N1IR

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-23 00:00:00 UTC
From: k1bqt@aol.com
Message-ID: <20001023195441.05419.00001131@ng-cb1.aol.com>
Source record: 177973

There is no formal notice or even a passing mention of copyright in N1IR's original article describing the M12. There is no mention of a copyright assignment to Chip or to FAS for anything. Nor is there academic attribution crediting the origin of the "Minkowski" fractal shape. Last I knew, Chip's last name isn't Cohen-Minkowski, so there must be an uncredited source for this graphic somewhere. But, we don't know where it came from. It just "appeared".

So, any judge will probably want to know if Chip sold first North American publication rights on copyrighted material and then failed to attribute that copyright to either FAS or to himself. The judge will want to know if Chip failed to state that the material was provided by him with the company's express permission and consent. The judge will have plenty of questions.

As Comm Quarterly readers, we don't know--nor could any reasonable person be expected to know--the answers to these questions. The article revealed nothing. Zip. Not a peep.

All we know is that Chip threatened to sue Roy back in September over material that he almost certainly didn't own the rights to at the time.

END QUOTE

The man clearly said that the application was shareware and that it carried a $20 price tag, which he paid.

Then you come in announcing that you do not use pirated software. Fair enough, though it does seem as though you are operating with a pirated brain.

Hey fracky,

I was refering to the fact that YOU were piss weak with the stations you were
talking to, and many of them told me that I was 20 to 30 dB louder than you were!!
And, I wonder how much louder I would have been if I had the amplifier on....

A question for you to ponder...
Why do you think that a "Q" rate on an open band without a contest represents
any indication of your performance under the gun in a real contest??? This is just
more of your huffing and puffing....must be your phd disconnection with reality....

Also:
I never made a "date" with you...you're not my type...you would need a sex change
and a brain change....

Hope this helps....

Hi Chuck--

Probably the reason I was so weak was that you hear me as groundwave and are off the back of the beam. The 10M Fractal Quad Yagi (see ham page on:

http://www.fractenna.com)

gives the all important specs.

Would you like me to post some of my runs from last weekend? I was on a total of 10 hours and filled a couple of logbooks--but of course, you know this because whenever I get on, you focus on LISTENING to me...must be a very good reason:-)! I'm flattered:-)

Note that I was working Europe only--and I am not using an amplifier.

Remember! We have a 'date' to compete in the 10M Contest!

Sorry; all the time I have at moment. Recovering from some severe flu bug.

Unfortunately, most of the "cooking" is being done by SW
broadcasters... It's a really different band than it was in the 70's
when I first got started in ham radio! I'm told that some good
filtering or DSP will help to make "nighttime-40" worth trying, but I
don't have that on my Yaesu FTDX 560....so I mostly avoid it and stick
to the lower part of 20m SSB in the evenings.

Well, what the heck did Mike expect from Copper Electronics? Their main business is the sell of radio equipment intended for illegal use in the CB band, which suggests they don't have a lot of respect for the law (so much for the character of the owners and employees).

In other words, if you're dumb enough to buy something from a sleazy company, then don't be surprised when that same company treats you in a sleazy manner.

Now, now, just because Cohen presumes [note: I do not like to use word assume to keep from making ASS out of U and ME] to use letters Ph.D does not mean he is trying to pull wool over anyone's eyes. Are you sure his intent does not mean Piled Higher and Deeper?

Linear steps from Associate of S__t; to Bachelor of S__t; to Master of S__t; to pinnacle of Piled Higher and Deeper.

I've definitely got to stop responding to this hogwash. Much like jammers, he gets off on his postings. If everyone turned a deaf ear/blind eye to his rants, he'd have to go somewhere else to start another brush fire to feed his ego.

Let's leave him to his own sandbox and not join in - unless you enjoy dropping down to his level.

I wonder if, in the interests of honesty, Cohen would condescend to list the court he has filed his complaint with, the filing fee, the court clerk assigned file number and the date of initial hearing.

In the interests of honesty, that is, not just ranting and raving.

And the ferrite rod has the annoying habit of being bi-directional and
not omni-directional to vertically polarized waves. How about a gyro
stabilized, rotatable ferrite antenna for cars!

I have no idea whether, and if so, how, this can be done inexpensively on a Windows machine. There is an excellent Macintosh program (by no means "crackware"!) which does just this. It is shareware and costs US $ 20 (and yes, I paid). Quoting from the file "PrintToPDF Manual.pdf" (which I would not be surprised to find was itself constructed using PrintToPDF):

> PrintToPDF is a shareware Macintosh printer driver that creates PDF (Adobe
> Acrobat®) files from within your application programs. You can create PDF
> bookmarks to your section and subsection headings, and URLs will become hot

> creates simple PDFs for a much lower price ($20).

The program is available at

<http://www.jwwalker.com/>

I should state that my only relationship to James W. Walker, the author, is that of a satisfied user.

Any file belonging to an application with both Windows and Macintosh versions (e.g., a Microsoft Word file) should be able to use PrintToPDF. Move the file to a Macintosh that has the corresponding Mac version of the application and on which PrintToPDF has been installed. Open the file there, select the PrintToPDF pseudo printer driver in the Chooser (normally the Chooser selects among different printer drivers for different printers), and "print" the file. The result will be a PDF file representing the original document. Since PDF files are platform

independent, once this is done the PDF file can be moved back to a Windows machine and used there. Be aware that PDF files are closely related to PostScript files and thus can be enormous (compared with their non-PDF ancestors).

Those Macs which have floppy drives (none made in the last several years) can read Windows floppies, and write to them. Newer Macs without floppy drives can accept Windows-formatted Zip disks (if equipped with a Zip drive), or Windows-formatted CDs (all recent Macs have CD ROMs or DVD drives). Of course the quick way to exchange files is over a network, or over the Internet (e.g. e-mail the file as an attachment). If you do the latter, make sure the Macintosh user realizes that your Windows e-mail program likely cannot understand the BinHex encoding format most frequently used in the Macintosh world, but can understand AppleDouble (which is essentially MIME encoding) when he or she e-mails the PDF file back to you. In the other direction there is no problem; most Mac e-mail programs can deal with all sorts of encoding methods.

This is an issue of ownership and piracy.

If I make a million enemies it will not change the fact that Roy Lwallen has broken the law; That Roy Lewallen is acting in the capacity of a pirate.

Please; several people have been trying to apply 'peer pressure' to say how horrible I look in this.

This is not a beauty contest. Lewallen is prating something that belongs to me. No one will dissuade me from this course; I find it offensive that some will try.

READ THOSE WORDS CAREFULLY

Please: if you are uncomfortable with that then sever contact with me. I, personally, cannot maintain friendship with those who advocate piracy, given my history of creative output and the fact that this is a legacy for my son, and I will not be here forever..

Mr. lewallen is a pirate. His commercial site contains unuathorized copyright material. HE MUST REMOVE IT.

Mr, Littlefield--

It seems to me that this whole affair can be easily ended for Mr. Lewallen by producing a document showing transfer of copyright to CQ Communications. There isn't one--I told you this.

As I have told you, I never, ever, ever, transfered copyright to CQ Communications. NOR WAS I ASKED TO.

This is a lie which only fuels an irrational and mendacious diversion from the fact which is:

ROY LEWALLEN IS A PIRATE who is ILLEGALLY publishing and distributing unauthorized copyright material.

Excuse me;

I DO NOT USE, NOR HAVE EVER USED, pirated material.

I DID NOT REQUEST , nor did not encourage, ANY suggestioins on pirated
software.

I was, and am, happy to pay for the least expensive means to write a PDF file.

It so happens that Acrobat had a free file available, which I uploaded from
their web site shortly after that post.

I DO NOT ADVOCATE, USE, OR ENCOURAGE PIRATED SOFTWARE.

Nathan Cohen, Ph.D.

Then accept that as a 'sick individual' I have a certain focus to protect property which belongs to me, or for which I have responsibility.

I will do any and all things that are legally possible to stop Mr. Lewallen from pirating copyright material. I will , as a matter of information, continue a wide and appropriately timed public notice postings on the internet to make all who might consider downloading the file illegally to realize that they are aiding breaking the law.

If this requires a significant posting effort over a wide range of sources, then so be it. The public notice will not be isolated.

Cordially,

NC

Nice job!

I am always satsified with the high performance, reliability, and just plain fun if the 10M fractal quad Yagi.

I have to continue to remind myself that hundreds and hundreds of Europeans CALL ME, when all I have up is this dinky, hi efficiency fractal antenna!

It is humbling.

I guess I better get me a federal job first. I have never said who I work for but it sure ain't the G. Are you threatening me again gosh I hate all that paper work.

As much fun as twisting your tail has been I have professional responsibilities which, unlike you, I take seriously so I'll have to bid you a fond adios for a couple of weeks. I know you will miss me but duty calls and I have a hamfest to do some forums at so I won't be free next weekend.

Don't despair folks perhaps I'll find a new and more creative way to latch on to the Chipster's tail. If I do I'll be in touch look for foreign posts.

834. PIRACY BY W7EL-EZNEC

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-23 02:20:13 UTC
From: fractenna@aol.com
Message-ID: <20001022222013.20675.00000972@ng-cu1.aol.com>
Source record: 178093
Body handling: HTML body converted to readable text

Nathan Cohen, Ph.D.) isn't getting any sympathy there, so I see he's taking it farther afield. Readers of that newsgroup who haven't put him into their kill files have been able to see the whole story develop, but for readers of this group who don't know the story, here's a brief synopsis.>>

Incorrect Mr. Lewallen. Remember that this public notice will be admissible in a court of law.

<>

This much is correct.

<>

That is absolutely incorrect.

Since 1996, I have provided OVER 200 copies of the MI2 file. My requirement has been that the file be for personal experimental use and not be distributed. The copyright must be used and attributed.

Here are some places I have offered and sent files in response to:

rec.radio.amateur.antenna
antennas@qth.net
NEC-LIST
fractalantenna@egroups.com

Because of the extraordinary harassment, I have , in the last six months, restricted distribution of the file to those who are members of the fractalantenna@egroups.com reflector. Anyone can join and anyone can request and receive the file--SUBJECT to the above requirement. EVEN NOW, as before, ANYONE can receive the file under the aegis of restricted distribution, copyright acknowlegdment, and the above rules.

AT NO TIME HAVE I NOT honored a request to provide the file subject to the above. AT NO TIME HAVE I IMPEDED comparison, scientific evaluation, or legitimate access to the file SUBJECT TO THE ABOVE.

<>

NOT to me!

<< which I posted as I had said I would, and with Steve's permission. (You can download them from ftp://eznec.com/pub/MI2. The file 0Notes.txt in that directory explains what each file is.) Among the files are one of the MI2 antenna which Steve created by measuring wire lengths from a picture of the antenna on Chip's web site, where he had directed challengers to look. Steve

accompanied the EZNEC files with text files (same name but .txt extension) which explain about the models. In the text file accompanying the MI2 EZNEC file, he fully credits Chip for its design.>>

THIS IS A COPYRIGHT FILE owned by me. IT IS ILLEGAL to publish, distribute and copy this FILE from the EZNEC web site.

<>

This is an illegal publication and distribution of a copyright file.

<< Chip sent me an email message requesting that I remove the file on the basis that it's infringing his copyright. I don't believe there's any possibility it's infringing any copyright so refused.>>

You are infringing on copyright Mr. Lewallen .

<>

I am not threatening, I am proceeding. The public needs to be on notice that you are a pirate who is ILLEGALLY distributing copyrighted materials for which you neither own nor have permission to distribute nor publish.

I am not a president of any company, and I know of no company named 'fractenna'.

<>

This is another extraordinary statement which will be admissible in a court of law.

I asked, and was granted, transfer of copyright. It was purely my initiative and request, with no discussion whatsoever along the lines you discuss.

<>

YOU NEED TO REMOVE THE FILE. It is illegal to distribute and publish this file by you.

<<. But I see Chip's action as nothing but bullying, and I won't be bullied. So the file remains. I encourage anyone who's interested to read Chip's "challenge", and if you have EZNEC, to download the files and decide for yourself whether he owes Steve $1000. (Sorry, the files won't run on the EZNEC demo -- the full program is required.)

I apologize for the leakage from the antenna newsgroup of this bizarre matter. It's sad enough that we have to put up with it there.

Roy Lewallen, W7EL>>

I will continue to promulgate public notices describing your piracy, as the legal affair proceeds.

Nathan Cohen, Ph.D.

Hmmm.... I doubt that would be resonant on 20M. I;ve picked 20M because that seems to be a preferred freq or DX.

Let me try something for 20M. It will certainly scale for 6M. But I suspect you may benefit from an easier solution. Drop me some e-mail on chipn1ir@aol.com and I'll come up with something by Thanksgiving.

837. Re: Calibration of Bird Wattmeters

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-23 02:32:19 UTC
From: "George, W5YR" <w5yr@att.net>
Message-ID: <39F3A2B8.8BD37A46@att.net>
Source record: 178096

Getting back to the original topic of this thread, I have noticed that my faithful Bird 43 is significantly in error on 20 meters. It reads 115 watts when the correct reading should be 100 watts. As far as I know, VHF and UHF operation is normal and readings are correct.

I have cleaned all the contacts and connections in the Bird that usually cause problems so I believe that the metering circuit is working properly.

I can only conclude that the 250-watt HF element is at fault.

Question: can these be calibrated in "the field" i.e., my workbench? I have never seen anything on this procedure and supposed that it was a factory-only affair. I do have an accurate r-f power source to use in a calibration procedure.

So, if anyone has any information on this, I would appreciate hearing from them. Lacking any inputs from this source, I will contact Bird although I am confident that their response will be "return it the factory."

Maybe I have it screwed up but I think at 100w out on HF there is no "official problem". As in ignorable. Supposedly gets a bit dicey if you plant a microwave rubber duckie in yer ear and I can understand that. There are "intructions" in the ARRL website about staying at least two feet away from ham power power transformers. Never mind all the welders who spent their lives hunched over hundreds of amps of AC. I had one of those, he died of orneryness at 94.

Source record: 178100

Meet the ENFORCER:

First the enforcer sold publication rights to a series of articles containing material he'd previously transferred the copyright to--and no longer owned.

Later, the enforcer attacked and threatened fellow hams for "fair use" of a portion of that material shared in the course of scientific inquiery.

Now, way after the fact, the enforcer procures a copyright to the material and acts as if he'd owned it all along--presumably so he can use it as a weapon in a nuisance law suit.

Finally, the enforcer complains because his actions create a PR problem that make him "look bad".

As the monkey said when he got his tail caught in the ringer, "OUCH, that's quite a stretch!!!"

What I'm waiting for is for Gentleman Roy to get a gut full of this
crap and hit HIM where it hurts with a SERIOUS suit for libel, slander
and damage to his professional reputation among whatever else a good
torts attorney can work up from all that has gone on here.
I'd imagine he's harvesting message headers with contents as we speak
for submission for his attorney to consider. Maybe Roy will wind up the
owner of Fractalcrap, INC and then he can - I started to say he could
just burn the building, but I don't think there IS a building. He'll
just have settle for burning the company charter. In any case the world
would finally be free of fractalcrap.

> morass of complex info.

I'm not sure who asked this, so please excuse me if I copied this to the wrong person. Ghostscript can be used to produce PDF files - and its free.

You can find Windows and unix versions on the web easily enough. First you must install a printer driver for a Postscript printer on your PC (you don't need to own the printer). Print your document to a Postscript file, then read the Postscript file with Ghostscript. Ghostscript has the option of printing to numerous output devices, from 9-pin dot matrix printer, so colour inkjects, PDF files etc.

My own Ph.D. thesis was written in Wordperfect for DOS 5.1. When I tried to convert to PDF files using Adobe's Distiller, I had lots of problems, with Distiller complaining about problems in the Postscript files. However, Ghostscript worked fine, as can be seen at http://www.medphys.ucl.ac.uk/~davek/phd/phd.html

Adobe's distiller does allow compression of the PDF files, which Ghostscript can't do. However, I still managed to get a 250 or so page thesis with lots of diagrammes into under 5 Mb.

As I have said, there are many who have LEGALLY downloaded the file . IT IS
AVAILABLE. But not through anyone but myself.

An injunction and suit against the SOURCE of the illegal download is the first
way to go.

Mr. Schmitt has posted an accurate copy of an e-mail I sent him.

Mr. Scmitt is a a developmental engineer/scientist at the detonation branch of Los Alamos National Laboratory. He is involved with nuclear detonations, a high security clearance position..

The wheels turn.

Do the link budget. This is only possible if you had your illegal QRO amp on
Chuck:-).

>A question for you to ponder...
>Why do you think that a "Q" rate on an open band without a contest
>represents
>any indication of your performance under the gun in a real contest???

A contest is always higherin Q rates,, because there are more stations to work;
getting a pileup on a US station without a contest is an extremely rare thing.
Can you provide any evidence to the contrary? Indeed, I will prove this by
being on the 10M Contest and beating you silly:-)

This
>is just
>more of your huffing and puffing....must be your phd disconnection with

>and a brain change....
>

You are a sick fellow. I am a married monoganmous heterosexual. The date is for
the 10M Contest.

Are you divorced? Why did your marriage break up?

Just out of curiousity, do you own a toupee? Does it help for the older guys
out dating again? What about getting rid of the coke bottle glasses?

I'm just curious to know as I do have some friends out on the prowl again
looking for tips.

What works for you Chuck?

oh no! how could i have missed a multipage full color ad for fractal antenna products???? at least i assume that fracky wouldn't settle for anything less. its funny though, i just went through the ad sections for sept/oct/nov and see eznec, various quads, the spider ant, isotron, hosenose, and a bunch of others every month, but don't see fracky... what name did he put it under, he doesn't seem to appear in the advertiser directory under any name i recognize?

I have LEFT the NEC LIST for a while. No one has EVER said or implied that i am not welcome or can't come back.

I just get so MUCH e-mail--most of it from hams blaming me for the state of their world--that I have to limit the input.

later on I will probably subscribe to NEC LIST again.

The copyright laws do not scale as per 'worth' especially, when the pirate--in
this case W7EL--attempts to set the price.

You take more quick turns than a UFO!

You asked me a question; I asked you the answer. So, which category of
copyright does EZNEC fall into?

Or is it not covered by copyright and is thus in the public domain?

It is under the cover on the slug. You will probably destroy the cover
getting it off the slug (probably why they recommend returning it to the
factory). I think it must be glued on. I have seen a few at hamfests
that have had small holes over the screw. They were probably made by
very carefully probing with a sharp object and finding where to enlarge
a pinhole.

Wayne:
The difficulty in giving a direct answer lies in whether there is any unexpected RF on the outside of the coax braid. In the case where a balun is effectively used, then it makes no difference, and the closer to ground the better. Let me rephrase that. The least inductance in the grounding path the better the protection. All the RF is supposed to be inside the coax, or on the antenna wire, so whatever you do to the outside of the braid should have no effect on the system. Unless there is RF on the outside of the braid, coupled there by the antenna. If the coax happens to be a half wave long between the feed point and the ground, it may become an excellent vertical antenna. If it is a quarter wave, it should decouple from the antenna. And so on for other lengths.

My IC-706 outputs maximum power into 50 ohms. Its power output
falls off on each side of 50 ohms.

850. More 'Challenge' files

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-24 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39F66BDC.89C72504@eznec.com>
Source record: 177823

More MI2 'challenge' files have been uploaded to my site. They are
random4.EZ, random4.txt, random5.EZ, and random5.txt, all submitted by
Steve Best, VE9SRB. You can get them from ftp://eznec.com/pub/MI2/, or
you can go to http://eznec.com and click the "FTP Site" link. The text
files give more information about the corresponding .EZ files, and the
0Notes.txt file at the same URL has more information about all files.
All files submitted to date are compressed into MI2.ZIP.

More information about the purpose of these files and why they're posted
can be found at the deja.com archive at
http://x76.deja.com/[ST_rn=ps]/getdoc.xp?AN=673944577&CONTEXT=972449784.1468334083&hitnum=
11.
Chip's original "Challenge" posting is archived at
http://x67.deja.com/[ST_rn=ps]/getdoc.xp?AN=657467296&CONTEXT=972215956.414253064&hitnum=1
7.

Caution: If you click either of the above links while viewing with your
browser, it might not take you to the desired location if the displayed
link is wrapped onto more than one line.

Although the 'challenge' officially ended on September 30, the questions
it raises are still relevant to the subject of this newsgroup.

Hi Steve,

It appears that your #1 point negates all other claims of copyright protection when those figures became part of public domain - again.

Absolutely ever other work is derivative and as the courts have adjudicated: data lists do not constitute copyrightable content. As EZNEC is based on a list of parameters, EZNEC files in and of themselves do not carry copyright protection. (They may contain trade secrets - but that cat is out of the bag.)

If we were to allow the argument for arguments sake, then the complainant would risk being sued by Roy for copyright violation. The reductio ad absurdum is that there were EZNEC files in existence long before the content that is found to be contentious. Hence that same contentious content necessarily contains copies of those earlier files and to claim copyright violation necessarily constitutes an acknowledged prior copyright violation of those same previous files.

The comedy of the absurd is not foreign to these topics though.

Try this:
7.000 to 7.150 is the CW portion of the band
7.000 to 7.060 - lots of CW
7.150 to 7.300 is the SSB portion of the band
there are a couple of nets
7.235 HHH net starts at 0700 utc
7.2385 another net in the evenings
Or, just tune around. :-)

Also pick up a copy of Monitoring Times that lists the english
broadcasts of various stations.

Jim,
That's an expensive way to use ladder-line. If the distance
to the 'outside' is fairly short (<10-15 feet), I'd run coax
outside to a good balun, then ladder-line to the antenna...

Phil,
Between the two, it would make more sense to use the 50 ohm
coax. That assumes that the transmitter's output is 50 ohms,
and the antenna input is close to 50 ohms. If the antenna and
transmitter are really close to 50 ohms, using 75 ohms coax
would mean something on the order of 1.5:1 SWR. I think it
would probably come down to the quality of the coax, and the
co$t...

Thank you for publicly acknowledging the fact that the MI2 EZNEC file I produced was done so as a derivative work under "fair use". As such, the file itself belongs to me. I would agree that the IP belongs to you and I would in no way ever infringe upon your ownership or rights in that regard.

You personally make the design freely available to hams for general use and evaluation anyway, so I'm having a real hard time understanding how you can claim any damages against Roy. The patents that you were given publicly disseminate the IP. As a result, the MI2 design, graphical depictions, drawings, etc. are all public domain. That's why patents provide you with protection against infringement of your IP rights. In my opinion, "copyrights" on the MI2 design as they would exist in an independently produced EZNEC file are long gone. You might have a case if someone were to directly reproduce one of your figures or the actual file that you created.

In any event, the Minkowski Island Loop (MI2) has been depicted in other publicly available works, the copyright to which you have no claim (at least it would seem). Namely, the US Government patent document (checked with an attorney on that one - infringement is the issue there, not copyright) and the UCLA Master's Thesis. Any EZNEC file created from the figures in the

UCLA thesis would have nothing to do with any copyrighted figures you created of the MI2 loop. In my opinion, you would have no copyright claim in the event someone created an EZNEC file from this document and then subsequently distributed it over the Internet. IP would clearly be a different issue and you need to start with UCLA to clear that up.

Steve

Philip de Cadanet wrote:
"---use 52 ohm or 75 ohm coax to feed a monoband HF dipole antenna?"

Depends on the height above the ground because the antenna`s impedance rises with the height up to about 0.4 wavelength. At 1/4 wavelength height to 1/2 wavelength height, 75 ohms is probably closer to the impedance the dipole presents to the coax. At antenna heights most often used by hams (significantly less than 1/4 wavelength) 50 ohms is usually closer to the impedance presented by the dipole.

Best regards, Richard Harrison, KB5WZI

871. Fractal Geometry Insignificant ...

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-24 00:00:00 UTC
From: VE9SRB <srbest@worldnet.att.net>
Message-ID: <R6mJ5.5238$UL.334510@bgtnsc07-news.ops.worldnet.att.net>
Source record: 177888

Although there is no dispute that the MI2 Fractal Loop performs or works as claimed and offers this performance in a reduced aperture, it is evident that the Fractal nature of the antenna geometry is not the significant factor in determining the antenna's performance. To verify this, an EZNEC model of the MI2 antenna was created as a method to determine the baseline performance of the MI2. The baseline MI2 performance at first resonance is as follows:

Fr = 15.155 MHz
Resistance = 28.4 ohms
Gain = 1.83 dBi
2:1 SWR bandwidth wrt 50 ohms = 1.05%

These results are very consistent with the claimed performance of the antenna as presented by the MI2 antenna designer.

About a month ago, several arbitrarily shaped antennas were designed (about 5-10 minutes of effort in each case) occupying the same physical aperture as the MI2. These antennas performed as well as and in some cases, better than the MI2. The EZNEC files and results for these antennas can be found at www.eznec.com under the FTP site.

To further prove that the Fractal geometry is not the significant factor is achieving performance, yet another arbitrarily shaped design was created and modeled in EZNEC. This antenna has a slightly smaller aperture size and shorter total wire length than the MI2. It is not a "meander" design (as defined by the MI2 designer) like two of the previous antennas that were subsequently dismissed by the designer of the MI2 antenna as not being able to work. This new design is simply an arbitrary, yet symmetrical, rearrangement of wire shape in the same aperture. This new design took about 6.7 minutes to create. Performance of the new design at first resonance is as follows:

Fr = 16.06 MHz
Resistance = 32.8 ohms
Gain = 1.91 dBi
2:1 SWR bandwidth wrt 50 ohms = 1.62%

Clearly, if a simple rearrangement of the wire into a non-fractal shape can result in similar or better performance, the Fractal geometry is not the significant factor in determining antenna performance. Although the antenna geometry will impact antenna performance, factors such as feed point location, total wire length, and aperture size are as and in many cases, more significant than the geometry itself. Models of this new antenna can be found at www.eznec.com in the FTP site (MI2 Folder) under the name of random4.ez.

Thanks! I've been brewing a 3 element 6 meter beam that
gives me only 50 to 50.9 at the 1:5 to 1 points. I wanted
a valid comparison. Interesting - I get 3 MHZ at the 1.5
points down around 43 MHZ. Scratching my head on this...
I've taken the antenna and tripod to a friends house 30
miles away. Got the same readings using his coax, his
return loss bridge & generator as I get using the MFJ 259
and my coax. Tried different lengths of coax, and different
distances between elements - all to no avail. We've
temporarily concluded something must be wrong with
the gamm match. I'm using 7/8" tubing, so I ought to
get at least as much bandwidth as you saw with the Arrow.
It's good to have confirmation that I'm not on a wild goose
chase!

This is not a fine-distinction. If someone makes a derivative copy for personal scholarly use that is under the category of "fair use".

HOWEVER--

Roy Lewallen has published and distributed this file on a COMMERCIAL WEB SITE without authorization; indeed, in DEFIANCE of the notification that he is breaking copyright law.

That is NOT FAIR USE and is pirating.

He MUST remove the file from his web site.

Now: I don't want lectures on this. I am well-versed in copyright matters. I have been involved with copyrights for 19 years and hold several hundred. I am versed in the law. I am further guided by IP attorneys who affirm my understanding of the law. The law is clear and unambiguous.

This is NOT some game. Before the first of the month, Roy Lewallen will received a registered letter demanding that he remove the MI2 file.

If he does not , then legal action WILL--repeat WILL be taken. This will be a costly and losing battle for him and it is unfoirtunate that he confuses COPYRIGHT law and OWNERSHIP with --as he says--"bullying".

It is NOT bullying. It is enforcing a RIGHT OF OWNERSHIP.

>"You always get back what you give"

Unfortunately you have given nothing.

First, the random1.ez file is a FRACTAL. Thus your point has no relevance here.

Second, random2.ez and random3.ez are concatenated end load MEANDERS which do not model accurately under EZNEC. Please show us the data which confirms, for example, the behavior of random3.ez as a REAL ANTENNA. You will find that the reactance and gain are very much different from the EZNEC model, as you have chosen very close-spaced meanders.

Next, you have, as you claim, done a "throw away" on random4.ez. Fine; I will look at it and get back in about a week with my comments on it.

The bottom line is you have made a scientifically untenable statement. Your assertion that fractal geometry has no significance is against well-known and well-documented peer-reviewed publications.

Just alluding to the random fractals, it is extremely well known, and well accepted within the scholarly and professional antenna community, that Landstorfer and Sacher, and Linden/Altschuler antennas are optimized forms within the a priori FOM's so chosen. Their optimization schemes made no ad hoc assumptions about antenna 'shape' and fully allowed for more conventional--and as you say--arbitrarily shaped-- antennas.

Those other antennas were losers.

What I can see is that you are TRYING to say is that the MI2 that you modeled--under "fair use" for your personal scholarly purposes-- does not produce as high an FOM as two models which you spent a considerable amount of time modeling and 'discovering'. In fact, as I mentioned two months ago, meanders are inferior to fractal end loads, a result published in 1997, and also reported at ACES and APS meeting that year. I have several fractal end load loops which easily have better FOM's than the MI2 file..

Even other MI2's--THINK ABOUT WHAT THE TERM MI2 MEANS before anyone makes ignorant comments please; it is NOT ONE ANTENNA, but is a FAMILY of ISLAND antennas incorporating rectangular motifs of second iteration--are better than the MI2 file which you reproduced. They most certainly have excellent bandwidths. The 10M one has a 2:1 SWR of about 1.5 MHz to a 50 ohm feed.

I will be happy to forward a picture and an SWR plot from a REAL MI2 being used by an N3.

Just send to chipn1ir@aol.com and title:

" MI2 / SWR PIXS"

In other words, I don't know what you are driving at. You seem to want to make some scientific statement, and yet your comments , being both profoundly ignorant in the use of proper wording, and the results, don't support anything.

Why don't you write up your stuff and have it peer reviewed? You may benefit from additional professional comments on a subject in which you are, at best, a beginner at this time.

In the meantime, have Roy Lewallen remove the copyright MI2 file; it is an unathorized and illegal publication and distribution from a commercial web site. No permission has been granted in this case.

What I have made is a statement that you don't like and can't deal with. My conclusions are based on principles as scientifically sound, in fact more so than the scientific principles you use to describe the performance of your designs. At least I went through the effort of comparing the MI2 antenna against non-fractal designs occupying the same aperture and having similar wire length.

The publications and articles that I have read simply describe the performance of Fractal antennas and various Fractal designs. The only comparison with other designs that I am aware of is against the "full size"

designs. I have yet to see detailed comparisons against non-fractal designs
of the same aperture size, having similar wire lengths, etc. etc.

In and of itself, this example is meaningless. Please provide all details
of the antenna construction. How high was the antenna mounted above
ground?. How was it was fed? Is this a feed point measurement? Etc. Etc.

If you provide a file I can check it out and then come up with a non-fractal
design offering similar or better performance.

Phil, G4ZOW wrote:
"---use 52 or 75 ohm coax to feed a mono band HF dipole antenna?"

50-ohm coax carries power at lower peak voltage than 75-ohm coax, and carries more before breaking down. 30-ohm coax would or could be the most capable of carrying maximum power were it available.

75-ohm coax carries power at lower current than 50-ohm coax, and thus has less loss. 77-ohm coax would be the least lossy were it available.

I think the output of a short monopole and typical loopstick are often comparable. The loopstick is preferred for portable applications because of better compactness and greatly reduced sensitivity to detuning from nearby objects which would require an additional manual control. Let's take a look at some hypothetical numbers:

Assume:

F = 1 MHz // operating frequency
E = 0.001 V/m // RF electric field strength, assumed vertically polarized

The effective height of a short monopole (without a top hat) operating against a ground image is one half it's physical height. Therefore the effective height of a monopole 1/2 m high is 1/4m. The voltage induced at the base of the monopole is the electric field strength times the effective height.

Vmonopole = 0.001 (V/m) * 0.25 (m) = 250 * 10^-6.

The antenna looks like a 250 uV source in series with a very large (>10,000 ohms) capacitive reactance. The antenna could directly drive a high impedance RF amplifier but is usually resonated with an inductor to provide front end selectivity and some voltage gain.

The magnetic field, H (A/m) is equal to the electric field divided by the characteristic impedance of free space, 120 * pi (ohms).

H = 0.001 (V/m) / (120*pi) = 2.7 * 10^-6 (A/m)

Assume the ferrite loopstick is 1/2 inch (12.7 mm) in diameter and long enough to achieve an effective permeability of 50 compared to free space. The permeability of free space = 4*pi*10^-7 Henry/m.

The peak magnetic flux density in the loopstick is the magnetic field strength times the effective permeability.

Bpeak = 2.7 * 10^-6 (A/m) * 4*pi*10^-7 (H/m) * 50 = 170 * 10^-12 (Wb/m^2)

The peak magnetic flux through the coil, PHIpeak, is approximately equal to the peak magnetic flux density, B, times the cross sectional area containing the flux.

PHIpeak (Wb) = 170 * 10^-12 (Wb/m^2) * pi/4 * (0.0127 (m))^2 = 21.5 * 10^-15 (Wb)

The voltage induced is equal to the number of turns times the time rate of change of magnetic flux in the loopstick. Assume N = 100 turns.

Vloopstick = N * 2*pi*F * PHIpeak = 100 * 6.28*10^6 (radians/sec) * 21.5 * 10^-15 (Wb) = 13.5 * 10^-6 (V).

The open circuit voltage across the loopstick is only 13.5/250 = 5.4% open circuit voltage at the base of the 1/2m monopole. In practice, the loopstick is almost always resonated with a capacitor which provides a voltage gain (proportional to the loaded Q of the resonant circuit) of between 10 and 50. The higher impedance of the short monopole makes achieving a loaded Q of much more than 20 problematical.

In the end, the monopole wins by between 10 and 20 dB as long as there is negligible capacitance between the base of the monopole and ground. As little as 100 pF of shunt capacitance to ground can completely negate the monopole's advantage. Of course in this day and age, low noise gain is so cheap that a few dB is of little practical consequence.

Contact Bird. It seems they are allowed to export now that the "Cold War" is over.

A German firm would probably respond with an engineer and a device at your door. A French firm probably would not respond at all. But, from the American firm, you will probably get requested literature and a catalog.

There is a chapter (No.10) in the Evans & Jessop VHF-UHF Manual published by the RSGB which covers reflectometers fairly well. The Bird`s accuracy easily surpasses expectations of the authors of Chapter No.10.

Source record: 177903

I was thinking about building a simple , short spaced (8 foot), two element beam for 20M made from wire as opposed to aluminum tubing. I have a design in mind that will use supports to get it up around 30 feet. My question is about feed method and matching. I was thinking about a reflector and a driven element fed as a dipole, I assume that will work. I am planning to fee it with 50 Ohm coax. Should I use a balun? If so, what type 4:1 or 1:1? I am confused because I have seen two differing articles and one says 4:1 and the other 1:1 . I assume that the center of the dipole would be close to 50 ohms and that 1:1 would be suffice ?

Also, I think I can get the two wire elements fairly close to be aligned with each other, but some sag might exist. How critical is the alignment before it adversely affects the performace, and my Yagi becomes Yagi-less.?

I'm scratching my head. Frac says yep, he agree's , it's a weak case,
but that everything else you said is wrong. Ok, lets review the
question.:

"So your claim is that it is a violation of copyright to produce a table
> of numbers which represent the dimensions of an antenna that is in the
> public domain, and for which radio amateurs and others have been
> publicly invited to build? "

Ok, we know hams were invited to build this, and compete against it. I
don't see how he can disagree with this statement. Which leaves the
first, where you ask him if his claim is that it is a violation of
copyright to produce a table of numbers which represent the dimensions
of an antenna that is in the public domain is true. He disagrees with
that. So that means he really agrees that it is legal to do this. If he
agrees this is legal, why does he keep pressing this? He's a confused
puppy. MK

893. Re: wire beam design ?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-24 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39F61F0F.28E7DCFC@eznec.com>
Source record: 177910

I recommend that you download the free EZNEC demo program from http://eznec.com. With it, you'll be able to model the antenna, and determine the wire lengths you need and the pattern you'll get. It'll also show you the feedpoint impedance. The impedance at resonance will almost certainly be less than 50 ohms. If it's less than about 25, you'd get the lowest SWR by using a 4:1 balun, connected with the low-Z side toward the antenna. Otherwise, a 1:1 balun would be best. I definitely recommend using a balun. Radiation from the feedline might otherwise degrade your front/back ratio.

Another option you might consider if the feedpoint impedance is too low is to use a folded dipole as the driven element. You can make this from TV twinlead. Unfortunately, EZNEC won't be able to give you a precisely accurate feedpoint impedance because of the dielectric, so you'd have to cut and try a bit. However, you could still design the antenna with EZNEC using a single wire driven element, then assume that the impedance using a folded dipole driven element would be 4 times higher when adjusted to resonance. Adjusting the driven element length to get the best match won't have much of an effect on antenna performance, so the EZNEC gain, front/back, and pattern results would be valid.

Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.antenna

You will probably need two beams. Most of them will not cover the wide frequency range. SSB is usually horizontal and usually below 50.300. FM is above 52 mhz and vertical.

Bart, WB6HQK wrote:
"In the end the monopole wins by between 10 and 20 dB as long as there is negligible capacitance between the base of the monopole and ground."

Why then does the ferrite loop stick seem to work so well by comparison with a few feet of wire?

Bart may not have included the enormous loss in coupling an antenna so short in terms of wavelength. All signal transfer schemes will prove very lossy in the usual receiver. The monopole will be a high capacitive reactance in series with a tiny radiation resistance. Not easy to couple efficiently into a receiver.

Best regards, Richard Harrison, KB5WZI

898. Fractenna Gets the REAL EXPERTS Involved now

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-24 00:00:00 UTC
From: Heath <radiovintage@hotmail.com>
Message-ID: <RxqJ5.18547$Xc.956073@nntp2.onemain.com>
Source record: 177915

URGENT NEWS FLASH !!!!

Fractenna has now made the ultimate move to silence all of the people
with half a brain by now posting his crap to the C.B. newsgroup.
Expected results and reports are as follows:
(1)YOU'RE WALL TO WALL AND TREETOP TALL(technical fractal lingo for I can
hear you across the street as well as with your $5 Wal Mart antenna.)
(2)YOU'RE HITTING ME WITH 40 POUNDS(technical fractal lingo for you are just
as loud as when on your dummy load.)
(3) JUST WAIT TILL I GET THIS THING 100 FEET IN THE AIR.(That will of
course have to wait till I can get my anechoic chamber up there too)(hmmm
Chip never told me if I needed to run a feedline too)
(4)THE REAL TEST WILL BE TO SEE HOW MUCH POWER IT CAN HANDLE BEFORE
MELTING.(after all if Chip is legal he can not even begin to approach the
output power of a C.B. station.)
(5) Chip publishes all of thes words and descriptions about it but I have
never once read what the overpass clearance is for it on an 18 wheeler.
Get real and live in the real world fella.Ten meters is a band any jerk
can work the world on with 50 watts and a $5 mobile antenna from Wal Mart
when the band is in.He can also be the loudest or even the only station
being heard due to propagation.
Put your antenna against the ones on 2 meters and above in real world
conditions day in and day out when the propagation is more reliable for
making such tests and claims.Put it on the antenna range at the VHF
conferences and show us some real world results that are of more substance
than theory and then I will be interested.If you are not willing to do that
then please don't waste the time of honest intelligent people who are here
to learn and help others in the spirit of amateur radio.

I am obigated to make public notice of Roy Lewallen's piracy with respect to his illegal use of my copyright maetrial. If that does not interest you thgen I heartily recommend skipping the post.

If you look at what was 'joined in' it constitutes comments wishing for my death; fraud;prevarications about ownership of copyright; etc.

Sort of the very best that some hams have to give it would appear.

For the sake of all your suggestion about not responding makes perfect sense.

The copyright laws do not scale as per 'worth' especially, when the pirate--in this case W7EL--attempts to set the price.

You take more quick turns than a UFO!

You asked me a question; I asked you the answer. So, which category of copyright does EZNEC fall into?

Or is it not covered by copyright and is thus in the public domain?

It appears that Reg wrote:
(on a flat line with no reflections) "The forward power measured at any point along the line is identical to the power delivered by the generator regardless of the generator`s internal impedance. Pl does not exceed Pg."

Exactly. There is no reflected power to subtract, and there is no other source of power in the system. The load power is always nearly equal to the generator power when the line is nearly lossless, and the power delivered to the load is always the difference between the forward power and the reflected power.

Dear Frac-
Please note- I have several files describing the so-called MI2 antenna geometry. NONE of these came from either your site, your controlled lists, or ** from Roy Lewallen, W7EL **.

These files were not from you, and are all a little different. They describe a cute little toy antenna, of limited performance. I have compared them to publicly posted descriptions of your antenna (from your web site). Note- I do not have, in current existence, a copy of any EZNEC file from you. THe file I got is non-EZNEC, and was for only a quarter of the set needed for analysis. pretty primitive, really.

THe question is- if I publish these in print media or on the net, showing that they, individually, are NOT what you claim is copyrighted, am I going to be sued? I hope that is the case, because I could use some of the $$ I could then expect to get from a counter suit.

This brings up another point- just what is the item that you have copyrighted?- Is there a registered copy, at a safe, neutral location, that can be shown to pre-exist any file you claim is a violation? How are we, (or a judge) to know that a file you claim is piracy is the same as yours, and therefore a violation?

An irritated, inquiring mind wants to know.

Hope this helps- have a good day.- Bill

Roy wrote:
"The capacitance of the coax acts as part of a voltage divider which reduces the AM signal from the rod. It`s specially made to have as little capacitance as possible to minimize this attenuation."

Right, except "coax" may not be the correct name for the high impedance cable. It typically has no supports to keep the center conductor concentric. Supports might increase shunting effects, so the very thin wire is free to flop around inside the insulated outer shield.

Unless he has filed for copyright with the Library of Congress, and
has a dated confirmation, or he has mailed himself the information in
a sealed envelope that has a dated cancellation, he really has no way
of proving his information has been protected since any particular
date. Any nitwit can put a little "c" in a circle on a piece of paper,
but the trick is to prove the date.

Yes. The Bird wattmeter is a very reliable instrument which tolerates
many excesses, but not all. It can be overloaded beyond its yield point.
It may also have some late appearing defect. So, readjustment may make
it read right at one point only to be off the mark at other levels.

Ah, so you're a law expert, as well as an antenna 'expert'! We see.
Evidently your skills in each area are equivalent.

Maybe you'll set new legal prcedent-where the plaintiff winds up owing
damages to the defendant. Without having to countersue for them. As a
juror on the case I'd vote for that.

Bob- Your conclusion is the normal one, but- we are not dealing with a normal individual. What I expect could happen is that he will copy someones file to his site (they only differ a little) and claim identity. This would be easy for him to do, since he controls the site. We know that there would be no legal standing to such an act, but he does not want legal standing, he wants "Uproar".

This would be in keeping with previous activities of the multi-lobed persona usually signing at Fractenna, whether it be N.C., Nathan Cohen, PhD, Chip, Phil, or N1IR. He lies, distorts, and eats flames like his mothers milk.

Hope this helps- Bill-W4BSG

necessarily true.

>73
>Chip N1IR

A very well done gain antenna installation on 40/80/160 here in the USA can and does provide 'pileups' or runs on USA stations for the USA station with one. That happens more often than what most folks would call extremely rare occaisions. I assure you these are generally *NOT* single element antennas, although a nearer coast-line site, especially one with salt-water ocean 'view' aperature in the desired direction has an enormous advantage.

By way of example, but, by far, not the only example of well done low band installations, is the W8JI site. I'll note that his site produces many instances of good runs on 80 CW, for example. In over 40 years of listening on the low bands, I can cite many others, such as the beautifully done site at W3TUP just West of Erie. His beautifully hand-tuned three element full sized four element 40 metter rotary array up over the 100 foot mark is well capable of producing beautiful examples of 'pileups' on 40. So does his 80 meter four square.

Another more exquisite, but now defunct antenna installation that did so for many years was the largest 40 meter array operation I've ever been able to document. The old W5RR installation on Collins Avenue in Richardson, Texas had four 150 foot towers with two three element 40 meter rotary arrays ring-rotated on each self-supporting pipe tower stand. All of them could be properly phase fed, step switched with coax delay segments around the circle, with the entire total of 8 rotary arrays syncronized and firing in echelon. I've heard that site generate many, many, 'pileups' from both European paths, as well as Asian paths, in non-contest events. For your note, in competition with it less than 200 miles away from it here in Texas, the difference in how you stack up against it in single band work with my puny four element phased vertical array on 40 is the difference of about three to four slots in the published rankings in the single-band CQ WW. Not much difference, in the long run, between the then cost of over a quarter of a million dollars for his array versus less than a thousand for mine, but .. sigh!

Another beautiful example of an internal land-mass site that is perfectly capable of generating huge (for that band!) 'pileups' on non-contest days on 80 meters is the magnificnt full sized three element rotary of Gerald Williams at K5GW, near Greenville, Texas. His labor of love, yes, love for the honor of it, if you happen to know the inside construction story if that array, is probably twice as effective 180-odd miles North, as is my 4 element phased array on 80 meters here.

I can cite many, many more of these low band efforts.

None of them are fractal in design.

They never will be.

Nor, will any other low band sites, that ever really compete with them, be fractal antenna based.

Even if there was a performance advantage - design model for design model - normal layout vs. fractal layout, the sheer physical cost of construction and maintenance of what you advocate, could never justify the use of the technique on the low bands - for competitive purposes.

As the frequency goes down, the cost to support your suggestions rises horribly. It's bad enough to do the job straight forward! Grin!

I assure you .. that simply exquisite 60 acres of rhombics down in Irene, near Jo-burg, South Africa put up by Dave Larson, and all those like it, could never have been done in a practical fractal design. Score for score, performance for the owner seen day in and day out, no low band antenna ever built fractally, will ever show up in the low band circuits, that will ever compete with any of these and many, many similar sites.

In essence .. lightning is self supporting! I remember, and share the humor of your response to me that it's the ultimate fractal! Chuckle

Man-made elements, the more convulsive they are .. are not!

Perhaps you might care to offer a thesis on where the cost of contsruction vs. the proposed performance rate of return has a second DV min-max turning point for your suggestions? At what frequency should we all not have to consider your suggestion as a worthwhile endeavor, cost come to shove?

GDRFC ..

--> Sleep well; OS2's still awake! ;)

937. Autotuners?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-24 00:00:00 UTC
From: Jim Pennino <jimp@mail.specsol.com>
Message-ID: <2j94t8.v79.ln@mail.specsol.com>
Source record: 178048

For a whole lot of reasons it would be a great pain to run twin lead into the house without doing everything you're not supposed to do to twin lead several times over.

One thought I had was to put an autotuner, such as an SGC, outside and run coax into the house.

Anyone actually done such a thing and have anything to say about pluses and minuses?

FWIW, the antenna at the end of the twin lead would look electrically about the same as a G5RV.

Reg Edwards wrote:
> Cec, just out of curiosity, how does your IC-706 behave at
> about 10 or 20 watts output versus changes in load.

For what it's worth, here's the meter readings from my MFJ-949E.

Forward Reflected
20 0
16.5 0.75
15 1.6

100 0
95 5
88 12
60 12

At full power it appears that the transmitter generates enough
power to keep the sum of forward and reflected power equal to
100w until the SWR reaches 2.5:1 after which it generates only
enough power to limit the reflected power to 12 watts.

Message-ID: <5BiJ5.8131$xJ4.259539@bgtnsc06-news.ops.worldnet.att.net>
Source record: 178051

Just as a matter of record, "depictions" of the MI2 Loop antenna sufficiently detailed to measure relative dimensions and create ones own NEC or EZNEC model can be found in the following sources (others may exist).

1) US Patent 6,104,349. A US Patent is not a "copyrightable" document and the US Patent office has all rights to reproduce and distribute the document. It is legal and fair derivative use of the patent to use the figures or any other information in the patent to verify patent claims, model the patented antenna's performance with EZNEC etc, so long as one does not infringe on the claims of the patent.

2) Communications Quarterly published articles as follows (copyright not clearly claimed nor indicated). Direct Reproduction of the article would require the publisher's permission. All IP belongs to the author. Direction reproduction of a specific figure would require author's permission. Measuring relative dimensions of the antenna from a figure to create ones own NEC or EZNEC model to verify antenna performance might be considered fair and derivative use. The created EZNEC model would then belong to the creator of said model.
- Fractal Antennas Part 1 - Nathan Cohen, Summer 1995
- Fractal Antennas Part 2 - Nathan Cohen, Summer 1996
- Fractal Loops and the Small Loop Approximation - Nathan Cohen, Winter 1996

3) Radiokit - elettronica, October 2000. Two figures of the MI2 are presented. One has dimensions and is clearly marked (c) 1999 Fractal Antenna Systems. The other figure has no clear copyright indication.

4) www.luminet.net/~wenonah/cfa/fractal.htm Figure of MI2 loop marked courtesy of RadioWorld Magazine

5) RadioWorld Magazine - September 1, 1999

6) Fractal Antennas - Design, Characterization and Applications. A Masters Thesis from UCLA (c) John Gianvittorio 2000. This was made publically available in March 2000 and the copyright for the images in the document apparently belongs to John Gianvittorio not FAS or Nathan Cohen???

The SGC is inherently an unbalanced device. Will you use a balun? If
so, you will have problems trying to design a balun to feed all those
high-resistance/high-reactance loades.

I have used an SGC-230 to feed a 32ft tall vertical and it worked well
on 40m-17m. It even worked to a certain extent on 75m - lots better than
most 75m mobiles.

> FWIW, the antenna at the end of the twin lead would look electrically about

In that case, it will work well on some bands and not so well on others.

Mr. Best:

The MI2 EZNEC file is copyright and held by me.

W7EL d/b/a EZNEC are under copyright violation in the publication and distribution of the file.

PLEASE talk to your attorney about this: It will have grave consequences for you at a later time to have made such misleading public statements.

Nathan Cohen, Ph.D.

I have an ALINCO remote automatic tuner. I look like an SGC with some of the brains removed. I had it in my shack for 18 mos, and used twin lead from there to my loop antenna outside. Last year I moved it to the garage. I have coax to the tuner, then twinlead to the antenna. Some people worry about the "unbalanced tuner" to a balanced feed line, I don't . It is important to use the ground lug on the tuner, and not depend on the frame or the coax to provide the safety and rf ground. The only difference I can tell from having it inside vs outside is that when it is colder than 0 F outside it may have to be left on a while before it will tune properly. I assume it has a bad joint that is cold sensitive.

Does it matter where along the length of the coax feed line that the outer braid is grounded for lightening protection?
Can I ground both the metal mast and feedline right at the antenna? (The antenna is an inverted V.)
or
If it's a wooden mast can I ground the braid at some point closest to the ground rod which may be 1/2 way to the transceiver?

956. Re: 50 or 75 ohm ?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-24 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39F5D515.63C2208F@eznec.com>
Source record: 178067

I've always used 52 or 75 ohm coax to feed mono band HF dipoles. Although coax has a somewhat higher loss than dry twinlead or ladder line, its loss is considerably lower than those lines when wet. (This is an important consideration in England and here in Oregon.) Unless the antenna is very far from the rig (well over 100 feet), the loss in properly selected coax line will be negligible. Coax can also be laid on the ground, coiled, run through wet foliage, and otherwise routed and handled without concern. If operated some distance from resonance, added loss due to SWR is unlikely to be significant over the range of SWR your rig will accept.

I recommend the use of a "current" or "choke" balun at the antenna feedpoint to prevent the outside of the coax from becoming part of the antenna. There are a number of designs which work equally well on a single band, including the W2DU type balun (a sizeable number of ferrite cores strung along the outside of the coax), one made by winding several turns of coax or other two-conductor wire on a single ferrite toroidal or rod core, or one made by making some coax into a self-resonant coil.

958. 40m listening freqs?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-24 00:17:31 UTC
From: Robert Joshua Chen <rjchen@Stanford.EDU>
Message-ID: <8t2ker$7bt$1@nntp.Stanford.EDU>
Source record: 177995

I just installed a 40m antenna and would like to get a feel for the band. Anybody have any recommendations about which freqs to listen to at what times (i.e., nets, rag-chewing get-togethers, etc.)?

Thanks,
-Robert

>> The company is willing to relocate candidates but, will give a preference
>> for Phoenix, Arizona based candidates.
>>

Now with internet and remote computing, this should be available to me working from my office and telecommuting to AZ.
Proof of my qualifications and resume is that I have nothing to do with Fractal antennas. Designed most gain producing antenna per boomlength (Razor Beams). If you are interested, please contact me about my fee/salary and other arrangements.
No job description necessary, tell me what you need, I will do it (or not).

Regards, Yuri, K3BU, VE3BMV

40m is not in the least bit "channelized" or "scheduled" or "organized". The
cw starts at 7.0005 and goes up, the digital modes are generally found at
7.050 and up, Stateside ssb is further up the band. 40m cooks between
sundown and sunup, hook that new antenna to a decent radio, tune, tune,
tune, LEARN and enjoy.

> But that's for a *very* sturdy pole.

You got me to thinking a bit more. They gotta be out there used for cheaper. So say ya need, for instance, a really decent quick-erect portable vertical. One of these poles could very easily be the next step up from a w6mmr Saint Looie Special. I just ran an analysis on how one of these poles might work on 3.5Mhz as a coax-fed wire-wrapped center-loaded vertical. The numbers come up quite decent. Needs radials of course. Pull it down, short the coil and it's a classic 1/4 wave 40m GP. Bag the coax and feed it with a real tuner and it would become a voltage-fed gain half-wave vertical dx killer on 20m.

Nathan believes in publishing email so here it is.
BTW do any of you guys remember my claiming to
work any particular place or in any particular field?

If this ploy doesn't bring me to my knees next he is going
to tell his Mommy and hold his breath until he turns blue.

Since he has already slandered Roy numerous times
how about setting up the Roy Lewallen Defense Fund.
We all kick in $100 or so hire some gunfighter lawyer
up in Massachusetts to clean Nathan's clock and
bank account.

As has been always been my policy I will not bother Nathan's
boss but that said I have no control over what you guys might
do. I don't care about Nathan's job I just like to poke fun at him
when he picks on my friends.

Nathan you really are an embracement to PhDs.

Mr. Schmitt:

This week I will be writing to the Director of the Los Alamos National

Laboratory (Dr. John Browne), and the two senators from New Mexico detailing
the harassment and libel which you have inveighed against me. These include
deliberate and malicious efforts to attempt to get me terminated from my
academic position, and false misinformation regarding whether I 'deserve' to
have the title Ph.D. , as well as false accusations that you are the inevntor
of fractal antenna technology.These will also detail the assertions you have
made stating that I am mentally ill.

I will describe this inappropriate behavior with the intent to ask the

question why someone with such a malicious and destructive focus against an
individual should be in the responsible position of being involved with
nuclear detonation development.

I have very serious concerns for my personal safety and that of the country
if you can make false assertions freely while holding a position with severe
and serious responsibility.

Nathan Cohen, Ph.D.

The guy asked about 40m so I limited my response to his query to 40m. Sure, 40 is a qrm "challenge", but it's also a great "boot camp" for a newbie. If he can handle 40 he can handle any band. Except maybe 160 and 80. I've run 40 with everthing from a Heath AT-1 with one crystal for 7.060 and a Hallicrafters S-40B back when to my current whizzy TS-940SAT xcvr and JRC NRD-545 100% DSP rcvr. But I'm not at all convinced that I'm having more fun now than I did back when despite the big-bucks gear. Being a cw op I'm pretty much unaffected by BC stations, I work right thru 'em. Personal perspectives and prefences get into the mix and it sometimes gets kinda difficult to put yerself in the other guy's shoes, etc.

>co$t...
> 'Doc

Don't forget that the 'transmitter's output' is NOT really 50 ohms (ie 50 ohms output impedance). It is more correct to say that the transmitter is designed to feed into a 50 ohm impedance (more correctly, 'resistance'). The true 'output impedance' of the transmitter will be quite a bit lower than 50 ohms.

If the load placed on the transmitter output is more than 50 ohms, the main thing that you will notice will be less power out. If the load is somewhat less than 50 ohms, you will almost certainly get MORE power out, but you will start to overload the transmitter, and this will show up as an increase of distortion. The difference between a 50 ohm load and a 75 ohm load is only a dB or so - so I wouldn't worry about it!

If you are offered a hundred foot 'off-cut' of really low-loss 75 ohm coax from your local friendly cable TV company, take it (and buy the offerer a beer!).

73,
Ian.

Hi Phil,

From one G to another it won't make a scrap of difference between 50 or 75 ohms. Just get the thing erected and call CQ.

If you are VERY pernicketty you still don't need a commercial tuner. Assuming the transceiver has an internal SWR meter, for one-band operation all you MIGHT need is a few turns of 18 gauge wire wound on a used toilet roll cardboard tube, and/or a 300 pF variable capacitor.

Fine details depend on frequency, could be anywhere between 1.8 and 30 MHz, which you didn't state.

But my advice remains the same. Just erect the 1/2-wave dipole as high above ground as you can manage, connect some coax of any Zo to the dipole centre, fire up the Tx and yak-yak into the microphone.

And disregard any unwarranted warnings you may receive about precautions to prevent a teeny bit of radiation from the coax feedline itself. Isn't radiation exactly what you intended to achieve? Who cares from what part of the station it is radiated from ?

Hello Peter. Your best bet would be to have a dedicated 6m vertical antenna and a 6m beam. You can run both antennas to a two position switch in your shack, which will let you toggle between them as needed. SSB needs horizontal polarization for the most part, but when the bands are up, anything will work for DX !! I have been using a Comet GP-15 tri-band vertical for 6 FM and have a 5 element M squared beam for 6 SSB. With my 100 watt rig, I have been able to snag over 150 grids and several European countries.

Good luck and 73,

Chris

Buzz, wrong. Not only were similar concepts explored years
earlier it now appears that the use of the term "fractal" used in
association with antennas predates any of Fractenna's efforts.

980. PUBLIC NOTICE Fractenna flauts Federal Law

Newsgroup: rec.radio.amateur.antenna

In the furtherance of his Jihad against Roy Lewallen some person using the Fractenna@aol email address has violated the CFRs by knowingly publishing Official Use Only information in a general news area of usenet. The page that contains this information is clearly labled prohibiting use of any of the information for any non-official purpose as well as the appropriate CFR citation.

It is highly unlikely that any legal action will be taken in this case

but this behavior does speak clearly to the moral climate at Fractenna.

To paraphrase George Orwell in 'Animal Farm' ,"All the animals in this newsgroup are equal some are just more equal." Since Chip will undoubtedly try to twist this let me interpret for his edification. What I mean exactly is, that while trying to enforce pseudoleagal bafflegab against any and all who do not worship at the alter of the Fractal God Chip feels no obligation to follow either the law of the land or the standards of decent human behavior.

Having had significant dealings with small children I am familiar with

Chip's behavior but my kids outgrew it by their 4th birthday it would seem that the Cohen's kids did not, at least in Nathan's case.

When a grown man acts in public like a spoiled 3-year-old I don't think it unreasonable to call in to question his metal state. This type of constant addictive need for attention is not a usual or common thing and my understanding of common usage American English the term for this is abnormal.

Please spare us the tirade about trying to protect your copyright. This has nothing to do with your copyright it everything to do with your abnormal, unnatural need for attention and acceptance. Get some professional help I'm worried about you. If you lived closer and/or had any history of doing more than blustering I would be worried about me.

>
> For what it's worth, here's the meter readings from my
MFJ-949E.
>
> Forward Reflected
> 20 0
> 16.5 0.75
> 15 1.6
>
> 100 0
> 95 5
> 88 12
> 60 12
==========

Completing the table by calculation we obtain -

Fwd Refl Load Refl.
Watts Watts Watts Coeff.
SWR
------- ------- ------- -------
----
20 0 20 0
1.0
16.5 0.75 15.7 0.213
1.54
15 1.6 13.4 0.327
1.97
---
100 0 100 0
1.0
95 5 90 0.229
1.59
88 12 76 0.369
2.17
60 12 48 0.447
2.60

Whatever the internal impedance of the generator, there is no error when the reflection coefficient and SWR are calculated from the forward and reflected watts.

This enables the accuracy of another in line meter, which indicates SWR and RC directly, to be checked.

It would appear you detuned the antenna system to give SWR's of 1.5, 2 and 2.5 But in which direction and angle the system input impedance departed from 50 ohms the measurements give no indication. In another direction for the same SWR's a different set of figures might be obtained.

Upsetting the SWR by varying Tx frequency is another way of doing it.

Thanks for the figures.

Reg.

I used gcc version 2.95.2 19991024 (release) also so I had better take a
closer look at the output. It will probably be a few days before I get
time to wring it out. I'll let you know if anything weird shows up.

No need to apologize; I am all to familiar with the evolutionary nature
of this sort of package. Of course good public domain libraries are
available these days which make the task a lot simpler. Too bad C
doesn't have a built in complex type :-)

It looks like you do a pointwise integration of the current
distribution. Should be more efficient given the constraints on the
current distribution.

Most readers have wondered why all the belligerant gibberish from
Fracky. I think that most have decided that he is engaged in either a
frantic attempt to scare off really serious anylisis of his brainstorms
so that the true facts, which will seriously damage his claims. of his
'invention' won't come to light, *or* he is truly a nutcase.

As time passes I lean more and more toward the second explanation as
the natural progression following the first.

You not only do not know how to spell non-sequitur, you do
not undertsand what it means. Not surprising, though. You do not
seem to realize that you have gone far beyond copyright infringement -
you have raised the stakes to libel and slander.

In point of fact, the write up in 73 magazine goes exactly
to the heart of the matter. An EZNEC file can be created
from the description in the magazine.

In a court of law those facts and the contents of the article prove:
1) That Mr. Lewellan had means other than "piracy" and "theft"
to create the file he posted.
2) That dimensional information required to create such a file is
in the public domain.
3) That you provided information to the author of the article; the
fact that it is your design is stated in the article.
4) That you have no record of claiming ownership of the information
at that time: there is no mention of any copyright, patent or intellectual
property rights in the article

In court, it is real simple, actually. You will need to produce
evidence that Roy pirated your file. Merely showing his file
and your file to the court, even assuming they are 100%
identical, does NOT provide evidence that theft was
involved. You will need to prove that each and every
publicly available document relative to fractal antennas
and containing dimensional information, COULD NOT have
been used to create the file. When you cannot prove that he stole it, you

are wide open to the countersuit for libel and slander.

It gets worse for you. He *can* prove that what you say
is a lie. He has written, public records here on the NG
as to the origin of the file. It was provided to him, by another
ham who says he developed it based on descriptions in the
public domain. That proves, to the court, and to the readers
here, that you are a liar and are engaged in slander when you
post those lies about Mr. Lewellan. You have been told,
repeatedly, that those files were provided to Mr. Lewellan,
yet you persist in the lies and the slander.

You love to stir up controversy here. What you don't seem
to realize is how pathetic you make yourself look in so doing.
It is sad to see you - a grown man - babbling foolishly.
You do yourself a horrible disservice.

996. HF attic antenna adivice

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-25 00:00:00 UTC
From: tegwilym@my-deja.com
Message-ID: <8t72k6ies1@nnrp1.deja.com>
Source record: 177737

I live in a condominium that has all the usual rules against antennas, color of curtains, pet....etc. I am trying to figure out what kind of antenna I could put in my attic that might work ok on the 10-20 meter bands. I currently have a vacant unit next door to me that was just sold, so I figure this would be a good time to sneak around up in the attic without anyone hearing me up there. I do have one of those "Cliff Dweller" slinky antennas (You can see one on Ebay if you search) in the hallway and can't get it tuned up to transmit. I am thinking of maybe putting that up in the attic or maybe just a normal dipole up there. I am estimating that I have about 50 or 60 feet of room that I can play with up there. The attic is pretty short, only about 30 inches tall at the peak of the roof.

I do have a QFH antanne up there right now for receving the NOAA satellite images on 137mhz and have had great results from that, so I know an antenna is possible up there.

Any ideas from any of you condo dwellers?

I have the impression that Chip would stand in a crosswalk with a semi barreling down on him and threaten to sue the driver for failing to yield, instead of getting out of the way.

A friend who works with surgeons gets frustrated because, though most are very intelligent, many have not progressed beyond about that same age socially. They try to solve all problems by intimidation and bullying. They would sue someone for leaving a bushel of lemons and fifty pounds of sugar on their doorstep, instead of turning to and making lemonade out of them. That behavior isn't the exclusive province of that group, of course. (The friend, fortunately, has a very positive can-do attitude, and freely shares the lemonade with all who would ask.)

Hi.

I'm trying to learn about Monopole or Marconi Antenna, but I haven't found so much information yet. I want to know about "radiation pattern", "ray angle", "directivity", "gain", "radiation efficiency", "efective area", "ray efficiency", "aperture efficiency", "radiation resistance", "bandwidth", "quality factor", "antenna resolution", "polarization".

Where I can find information about equations and all this stuff in the web ?

Thanks.

>Kirkby`s experience is atypical.

Hi Richard,

To quote another Doctor, Samuel Johnson LLD

"The triumph of hope over experience."

Richard, these assessments from Metrologists (now two here in this board) do not denigrate the robust design and general applicability, they simply point out that the determination of RF Power is extremely difficult if your objective is accuracy. Bird meters do not qualify as accurate except for the most lax meaning.

On the other hand accuracy is not necessary for day to day operations, whereas repeatability and ease of use are. The robustness is probably the only asset to be found.

Where accuracy counts (for the FAA or FCC), the law mandates that such instruments be calibrated and seals affixed and certificates made to indicate the exact nature of usage. This is neither the common practice nor the common experience of the Ham OR EVEN PROFESSIONAL. It does not alter that it is the common hope.

Reg wrote:
"Ferrite rod antennas are the most inefficient antennas imaginable."

Ferite rod antennas are loop antennas. Loops must approach a perimeter of a wavelength, according to Terman, to be efficient.

I however recall the post-WW-2 era when traditional air-core loop antennas were replaced in broadcast receivers, not just for size reduction, but to boost performance, too. In the U.S. the Grayburne Loopstick appeared for aftermarket retrofit of radios with the new ferrite rods in place of the obsolete air-cored loops.

Keith Henney`s "Radio Engineering Handbook" says:
"An iron-cored d-f loop promises to improve performance in addition to reducing the size of loop antennas, 150 to 1700 KHz. (P 883)

I think the iron core`s permeability multiplies flux and reduces turns for a given inductance which cuts the copper loss. The lost coil area and fewer turns are more than offset by the increased core permeability.

Best regards, Richard Harrison, KB5WZI

Are you aware that the IC-745 uP program is stored in dynamic
RAM and if the battery runs down the transceiver stops working?
Do you know whether the dynamic RAM program is operational or not?
Even if there is a power surge and the RAM gets changed, the 745
will fail. I had one for many years.

I've seen some that use wooden spacers to hold the elements together at
the right spacing. You can design the antenna to have pretty much any
feed you would want. Depends on the spacing of the elements. I think I
would design for a appx 50 ohm feedpoint and just go with the 1:1 balun.
Actually, I was looking at a few of these on eznec demo the other day. I
made a 2 el beam that had a nearly perfect 50 ohm feedpoint. About 47
ohms if I remember right. The use of 4:1 baluns will usually be used on
yagi's that are designed for maximum performance.
The feedpoint impedance will usually drop to the 15-20-30 ohm range with
an optimum spacing for max gain/FB ratio.
The design of a yagi with a 50 ohm feed a slight compromize in
performance usually, but I doubt you would notice much difference in the
real world. For a simple 2 el wire beam, I'd keep it simple and design
for a 50 ohm feed, and use the 1:1 balun which can be as simple as a
choke. Easy to deal with. MK

The 17-meter band on my HF9V required a drastic departure from the directions in order to get it to tune. I think that the coil ended up compressed to about 1/2 the length called for in the instructions.

Just do with the coil whatever it takes to get the minimum SWR point where you want it. But, check the other bands for any effects. With any multi-band antenna, any one adjustment ripples through the entire system causing anywhere from negligible to major changes in other bands.

As I recall, both 12 and 17 were pretty far off with the basic instructions. But both tuned well with a little more effort.

As a practical matter, it is probably not worth a lot of time and effort to get every band under 2:1. Your rig tuner can easily handle that and take the antenna system impedance down to 50 ohms within the transceiver.

Thanks for the background and advice, David.

I think that I will just let things alone and rely upon other better
calibrated power meters for detailed work.

I guess it just "gets me" that the comparatively low-tech metering
circuit in my MFJ 989-C tuner can track the output of my Kachina from
100 watts down to a few watts and be right on the money to within a
needle width at all power levels. The Kachina output power is regulated
digitally to within a small fraction of a dB. It also tracks the meter
and digital/panel indications of the IC-756PRO quite closely as well.

You might be interested in the "Field Day Special". It's a
ZL-special-like antenna -- two elements spaced 8 feet apart on 20
meters, made entirely from 300 ohm twinlead. It has a very good
front/back ratio. It has a fairly broad forward lobe, and you can
remotely reverse the pattern, both of which are convenient if you can't
rotate it. I've used them for Field Day for many years, as well as from
the home QTH. You can get full information, and a simple program for
designing this antenna, from ftp://eznec.com/pub/, or by going to
http://eznec.com and clicking on the FTP Site link. The file is
fdsp~.exe. "Running" it expands it into several files, including
instructions.

Richard Clark wrote:
"Bird meters do not qualify as accurate except for the most lax meaning."

We are fairly lax in the U.S.. The FCC inspectors on visiting the stations where I worked would accept the thermoammeter common-point reading along with our declarations of measured impedance at that point as definitive of the transmitter power output. They would at times also make fieldstrength measurements at our designated monitoring points, for power verification. antenna efficiency, and compliance with null impositions. The FCC didn`t require any seals, stickers, or traceability to standards. They did approve frequency standards and modulation monitors, as I recall. We also employed a frequency monitoring service to wire us a report every month to compare with our logged reading at the service`s measurement time.

Every two-way radio shop I ever saw, including those operated by radio manufacturers as company stores, used the Bird wattmeter as a power measurement standard. For microwaves they would use the appropriate H-P test set.

The radio manufacturer wouldn`t tolerate a power meter that read low on power any more than an auto manufacturer would tolerate speedometers that gave low indications.

On the other hand, a radio manufacturer wouldn`t want a wattmeter that read high because customers would ask why such a powerful radio didn`t talk farther.

Manufacturers and users also have maximum FCC licensed power restrictions that demand compliance. The inspector`s power meter had better be scaled the same as the licensee`s.

My experience has been, that if Link, RCA, GE, Motorola, or whoever said the radio would put out 500 watts, it sure did with a little extra in reserve. Anybody`s trusty Bird wattmeter would give very nearly the same reading in measuring that output in that instance.

I think Bird is truthful in their accuracy claim. There are many reasons other than a poor sample being measured to find inaccuracies. Bird gives quite a list starting with the standard against which the sample is being compared. There is the signal being measured which must be a clean sinusoid with no spurious signals attached. Temperatures must be controlled. The right media must be properly used, and it all will fail if the operator doesn`t know exactly what he is doing.

We have two metering experts testifying that they`ve found the Bird wattmeter very short of the claimed accuracy. I don`t know how many samples they`ve tested. I`ve seen thousands of measurements with no reason to question the results. Questionable slugs have been rare indeed.

But, it happens. You can`t put 10000 watts throough a 1/10-watt slug without the possibility of damage.

I own no Bird stock and I don`t know anyone who works for Bird. I`m not loyal. I`d buy something else in a heartbeat if it were cheaper and better. I never thought I`d be defending something I thought was common knowledge. The Bird isn`t just something that works well, it`s about the only thing that conveniently measures power in the field accurately while the equipment being measured is operating, (normally?)

Best regards, Richard Harrison, KB5WZI

Hi Richard,

I've seen the same thousand, and qualified (the less encompassing version of calibrated) all of them. Absolutely every Bird that came through the door failed to meet standards. There is no way on god's green earth that any casual observation will reveal accuracy or inaccuracy in any reading.

But really, this is of no importance. Most measurements of power are not concerned with absolute accuracy, just relative accuracy. Taking the same out of spec Bird and measuring forward and reverse power suffers equally and after a fashion balances out. Birds are robust and good service monitors, but are not absolutely accurate.

And George, your Kachina probably exceeds the accuracy of the Bird, but using a Bird to prove it is rather getting the horse before the cart. Now when I say accurate, as he stated that the settings offered correlated good readings, this only proves the scale linearity of both instruments, but says absolutely nothing about absolute accuracy. The one relative to the other offers very good evidence of relative accuracy, which for his purposes is more than adequate. However, observing a new out-of-the-ordinary reading is suggestive, but lacking a third (non-Bird) standard, it is simply a coin toss as to where to point the finger at the offending device. All should note that this out-of-the-ordinary reading is still within the so-called 5% specification from Bird.

> Andy KB2EOQ

I ran your antenna thru eznec real quick to see what would happen being
stuck with a 8 ft spacing. I came up a with an optimized design for that
spacing. IE: gain vs FB ratio. The best match I could come up with to 50
ohm line so far was about 1:8 to 1 using a 52 ohm coax.

EZNEC Demo ver. 3.0

10m2el 10/25/00 3:36:01 PM

--------------- SOURCE DATA ---------------

Frequency = 14.15 MHz.

Source 1 Voltage = 27.76 V. at 3.89 deg.
Current = 1 A. at 0.0 deg.
Impedance = 27.69 + J 1.882 ohms
Power = 27.69 watts
SWR (50 ohm system) = 1.809 (75 ohm system) = 2.710

The feed impedance about 27 ohms. You could run this direct if you had a
non picky tube rig, but solid state you would want a little better
match. I could get a better match, but need a wider spacing. This design
has a good F/B ratio for a 2 el. Abt 10 db. About 6.5 dbi gain. Would
make a fairly good 2 el I think. And if you used wood spacers at each
end the antenna could be flipped in the opposite direction. But I guess
would be kinda of a pain. I made an image of the azimuth plot you can
see here: http://web.wt.net/~nm5k/20m2el-1.jpg
I kinda think this would be a good one to try if you need to keep the 8

ft spacing. But you need about a 2:1 ratio balun or whatever matching scheme for a perfect match. I also am posting the ez file.
http://web.wt.net/~nm5k/202elsp.ez

If you have or d/l the eznec demo you can run this antenna, and modify if needed. It's pretty easy to get one dialed in. Took me about 10 min for this one. The antenna uses #14 wire for lower weight.

I would try a dipole, feed with ladder wire. Make the dipole as long as possible, and remember to keep the ladder wire away from metal.

All I can say is that we were a calibration lab, with temperature and humidity accurately controlled. We were a government lab, with standards that were internationally traceable. This was a whole different level of accuracy compared to transmitters whose output power possibly depended on temperature, mains voltage etc.

> + or -5% is not claimed as laboratory accuracy. But, compared to any
> other commonly available field measurement RF wattmeter, the Bird
> deserves the reputation it has with amateurs and professionals alike.

I'm not saying Bird claim +/- 5% is laboratory accuracy - what I am saying is that few meters meet that 5% spec. Most meet +/- 10% of FSD, but few meet 5%. The number failing to meet +/- 10% was not small, but I can't recall exact numbers.

For what it is worth, I've met other professionals who share the same opinion as me. I bought a Bird 43 as a ham and when a much older ham told me they were not very good, I did not believe him. Perhaps I did not want too, as I was at school at the time and a Bird 43 was quite a financial investment for me. The chap who told me this had worked for the Ministry of Defense too.

I'm not active now, but if I did become active again, I would probably buy a Bird again. They have an accurate 50 Ohm section of line (unlike most ham meters) and are accurate enough for most amateur use, but accurate to +/- 5% of FSD they are not.

I think we will have to agree to differ.

A Bird 43 running *near full scale* that has 5% of full scale accuracy can in principle be off by 0.2 dB. Isn't this plenty good enough for most practical purposes?

One other thing. If a mfr guarantees 5% of full scale as it leaves the factory, it had better be substantially better than that during assembly. Else at the factory inspection station the number of rejects will be as much as 50 percent. This would be intolerable for any mfr. The tail of the probability curve should be quite small beyond the 5% level. This makes the "expected" accuracy more like 3% of full scale.

It's my understanding also that wattmeters with digital readout are more accurate and that a lot of the error rating is budgeted to the D'Arsonval meter.

Ian Jackson, G3OHX wrote:
"If the output impedance (resistance?) of a transmitter was equal to the load, a transmitter delivering 100W of power would dissipate at least 100W in its output stage."

Exactly the argument I made again and again on this newsgroup. Dr. John Fakan privately went to great lengths to show me I was wrong. But, I just didn`t get the idea of a lossless resistance controlling the output of a Class-C amplifier despite marvelous water-wheel analogies and the example of a marvelous electrical machine the good doctor had built for NASA.

Then it dawned on me. It was possible to have a dissipationless resistance to limit the flow of electricity. No energy storing reactances, nothing more than a perfect off/on switch. You increase resistance by increasing the % of off time during a regular switching cycle. This can be at a radio carrier frequency rate. The intrruptions can last for a large part of the cycle, in which case the effective resistance will be high, or the interruptions can last only for a short part of the cycle, in which case, the effective resistance will be low.

The Class-C amplifier is just such a switch but it is imperfect. Most of its loss comes from a finite resistance while switched on.

The internal resistance of the Class-C amplifier is thus made up of two parts, the resistance from its switched-on loss and the lossless resistance from its off/on cycle which creates its average energy flow. The sum of these two resistances is the output resistance of the Class-C amplifier.

The last time I posted this theory the silence was deafening. It probably comes from the idea that the insane had best be humored.

1. Only over a very narrow band of frequencies will most any antenna be purely resistive. There will all most always be some reactance in the antenna system.

2. Depending on tube or transistor finals in the transmitter you either start with a very high impenadance value (say around 800 volts at 200 ma for a pair of 6146 or similar tubes for about 100 watts output) or for transistors a very low one(12 volts at around 20 amps) and that is transformed by a matching circuit to whatever the antenna is for maximum power transfer. The output circuits must be designed to transform this value to whatever the antenna (load) is for maximum power transfer. Usually 50 ohms for modern transmitters.

It also doesn't switch instantaneously, so there is some non-zero loss
during the transition. You're on the right track, though. The efficiency
of the class-C amplifier is determined by these losses and has nothing
to do with any supposed amplifier source resistance.

> The internal resistance of the Class-C amplifier is thus made up of two
> parts, the resistance from its switched-on loss and the lossless
> resistance from its off/on cycle which creates its average energy flow.
> The sum of these two resistances is the output resistance of the Class-C
> amplifier.

Except that, as you pointed out, the resistance varies over the cycle.
So what is the "real" resistance? That's a hard question to answer.
Resistance is, by definition ("you could look it up"), a property of a
linear system that does not vary with time. The transfer function of a
class-C power amp is neither linear nor time invariant. So a compelling
argument can be made that it has NO definable resistance. (Consider that
if you applied a sine-wave signal to the output of a class-C amplifier
the resulting current would not be a sine wave. Thus the current

contains frequencies other than that of the applied voltage. Now, think about that. How do you use Ohm's law to compute resistance when the current and voltage don't even contain the same frequency components? Answer: you can't.)

Practically speaking, of course, the interesting question to the amplifier designer and user is what LOAD resistance (impedance) allows the amplifier device to operate safely and efficiently. There is no simple relationship between that value and the device's on/off resistances and duty cyle. It's device dependent.

In short, arguing about the source impedance of a non-class-A amplifier is pointless. Trying to relate source and load impedance with amplifier efficiency is even worse. You just can't reduce nonlinear, time-variant systems to Thevenin or Norton equivalents at will.

Ian Jackson, G3OHX wrote:
"I have always understood that the output impedance of a transmitter is pretty low (compared with the design load) and pretty reactive (i.e. non-resistive)."

The transmitter`s internal resistance would need to be low to get the typical Class-C efficiency were it not for lossless internal resistance from the transmitter`s high % of switched-off time. Otherwise, the transmitter`s internal resistance would have to be low as an electric power generator`s internal resistance must be low, as compared with its load, to get efficiency. But, by using lossless internal resistance and an unavoidable amount of lossy internal resistance, even maximum power transfer can be achieved with an efficiency exceeding 50%.

Most Class-C final amplifiers are "dipped" for minimum current, parallel resonance in the tank circuit, maximum (very high) tank impedance, and zero net reactance (a pure resistance) in the amplifier`s output.

At resonance, the tank has nearly disappeared, its impedance is so high. At other frequencies its impedance is very low so that only the fundamental frequency has any significant strength. It is "linear", that is sinusoidal, and the only load it sees is the transformed value of the transmitter`s ultimate load.

Jacketed hardline (Heliax type line) is rated for direct burial. It is fairly common practice at MW broadcast sites. The usual cautions apply (no sharp rocks, sufficient depth etc.). However, if the run isn't too long, it is wise to put in conduit so that you can replace the line if it has a problem or add a second line later for another antenna. If you don't, you may end up hating yourself in the morning. (c:

I am not familiar with the Atomic Clock construction, but the Rat Snack clocks made by Oregon Scientific have a short pendant that contains both the loopstick and the receiver. The cable has four wires - V+, Vcommon, turn on, and signal. The signal is 1 Hz square waves of varying duty cycle, so extending the cable is not an issue. Perhaps the Atomic Clock has a similar arrangement where the receiver and antenna circuit are separate from the clock circuit, even if they are in the same case.

Signal strength doesn't seem to be the main concern as to whether these clocks synch up or not. The prime culprit is noise. TV's, computers, dimmers, touch lamps etc seem to be the biggest offenders. Perhaps relocating the clock will help.

I have no trouble with my Rat Snack clock here in Portland.

YOU are the one that said that FAS held the copyright of it during that time and that it was JUST transfered back to you on the 21st (I think you said) of this month.

1057. Low Profile & Quality Peformance mobile antenna, possible?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-25 00:00:00 UTC
From: Nick Carrigan <nickcarr@earthlink.net>
Message-ID: <BBvJ5.17465$1S5.1635424@newsread1.prod.itd.earthlink.net>
Source record: 177854

I drive a BMW, and I am looking for the best dual-band VHF/UHF mobile antenna, that won't "advertise" my radio -- BUT, I'd like to get the perf gains...

(I don't know how good these 'quality' magnet mounts are either. It makes me nervous to think about what they do to paint. An old R/S 2m mobile ended up rusting my old car. I'm thinking of a trunk lip mount.)

I've tried those window mount antennas before (like the one from R/S). That thing was a waste of $$$. I couldn't even get the WX channel from my rig after that. Have these types improved at all??

Should I just spend the $100+ on a name-brand mount + antenna for will be a trunk lip mount?? Can I cut a few corners here without ruining my car?

If anyone has any suggestions, then please pass them along...

Thanks
-Nick

PS. Getting rid of the B'mer is not an option! ;o] (I already had a gas-guzzler SUV...)

OK: Let me ne exp[licit about this.

FRACTAL GEOMETRY ALLOWS FOR LOOPS WITH THE HIGHEST FOM.

Unlike Mr. Best, I WILL submit results for publication., under the title

ELECTRICALLY SMALL BROADBAND FRACTAL LOOP.

This will be submitted for publication before 1 January.

In the meantime, the evidence is clear that BOTH Mr. Lewallen and Mr. Best are using this bogus assumption to AID AND ABET in ILLEGAL DISTRIBUTION AND PUBLICATION of copyright material.

Nathan Cohen, Ph.D.

Because, Steve, YOU ARE DELIBERATELY ENCOURAGING SOMEONE TO BREAK THE LAW and DELIBERATELY ATTEMPTING TO MAKE THE VALUE OF MY INTELLECTUAL PROPERTY WORTH ZERO.

NO ONE AT ANY TIME has disputed that it is LEGALLY POSSIBLE TO OBTAIN a copy of the MI2 file FROM ME.

This is not an issue of science--that is and will be easily settled by publication--but your DELIBERATE AND OBSESSIVE FOCUS to misinform and now to encourage COPYRIGHT INFRINGEMENT.

You keep on saying you will make "your last post' and then you just make it worse.

This is rapidly becoming the #1 topic of the antenna community. You seem to feel that its a 'truth' issue. In fact it is; the TRUTH is OBEYING LAWS and HONORING THE INTELLECTUAL PROPERTY OF OTHERS.

Why would I possibly care if you posted 1000 files with alledly better FOM's than the ham Mi2 file? Don't you think that I enjoy the challenge myself?? You have made a perversion of it by HELPING AND ENCOURAGING LEWALLEN TO BREAK THE LAW.

>
> Phil G4ZOW

Hi Phil,
In most cases the difference in neglegible. Most dipoles have an impedence that ranges ruffly between 35 and 90 ohms dependant upon height above ground and surounding influences.. the differences between putting a 75 ohm line to a 50 ohm antenna is only on the order of 1:4 to 1 Swr. Not enough with most rigs to make any difference.

Wow... with a ground like that you will get great performance...g'luck
with it.
I found the 12 and 17M coils are very touchy... it doesn't take much to
detune them as they have very narrow bandwidth. You may need to move
the position of the coil on the verticle up or down a bit besides
tuning the coil length. An antenna analyzer or a xmitter that xmits out
of band is a big help in finding where the coil is tuned and which way
to move it.

Message-ID: <39F6D055.5B3BD8DD@medphys.ucl.ac.uk>
Source record: 177867

Hi Bart,
I'm glad it compiles and runs okay on Free BSD. There seems however to be a problem with gcc-2.95.2 (not 2.85.2 as I stated earlier) under linux PC. Someone bought this to my attention and I've since seen it Given it only happens with the optimiser selected, I think this points to a bug in gcc. Without easy access to a linux PC, I can't see if I can alter the source to eliminate the problem. I've often come across compiler bugs that can be eliminated by changing a few source lines. Declaring an integer static instead of just int used to solve many a bug in Microsoft's old C compilers.

The source is a bit confusing at times, partly since the routines I used for solving the complex matrix problems use routines designed for real number, not complex one. I also moved things around in arrays a bit more than was needed. Some stuff gets put into an array for parasitic elements and some more into an array for driven elements. It would have been much more sensible to put them all in the one array, since it needs to get put there anyway later.

The file self2.c calculates the self impedance of an element and the routine z21 in mutual.c calculates the mutual impedance between any pair of elements. Once you have this data, the driving point impedance is found from inverting a matrix. One then finds the drive current. I'm not quite sure how the gain is found from this (memory escapes me), but I suspect it relies somewhere on the fact the far field radiation pattern is the FFT of the current distribution. Just doing an FFT on the currents are summing the resulting radiation pattern would given the radiation in any direction. I would need to double check that though - I wrote the code about 6 years ago, and have not done anything with it until about a month ago, when I mainly provided better documentation, but not changed the code much.

The routies that plot the results need gnuplot installed. They plot the graphs on a log scale, which makes the patterns look much worst than people are used to.

1074. Re: Calibration of Bird Wattmeters

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-25 00:56:36 UTC
From: "George, W5YR" <w5yr@att.net>
Message-ID: <39F62F44.7133D921@att.net>
Source record: 177829

Folks, I hate to appear totally "dumb," but *where* is this calibration adjustment that everyone mentions?

I can find nothing on the case proper to adjust other than the meter zero-adjustment screw. The only other possibility that I can see would be the thin metal cover over the front of each slug. It appears to have been seated with a blow with a centerpunch (to account for that mark in the center of the arrow). This cover does not want to come off "readily" but I have not really been very aggressive in trying to remove one.

So, any help will be appreciated.

For the PRESIDENT of CUSHCRAFT to continue to ignore peer reviewed fact indicates an agenda.

If he had no agenda, then:

1) why would he continue to encourage a "fair use" copy to be published and distribute OUTSIDE of that limitation?;
2) Why does he say that 'this is my last post' and then continue posting misinformation?;
3)If what he says is TRUE, then why has he not published said info? In the time he has spent providing incorrect and misleading information, he could have had a paper published in Electronics Letters.

No; this is not science. It is a competitor dead-scared of a disruptive technology which will not eat, but devour, market share in markets he is trying to penetrate.

Misinformation and propaganda makes for good business--or so it would seem from Mr. Best. This is Cushcraft's position, isn't it Mr. Best?

Source record: 177835

I have just put up a Butternut HF9V at ground level and installed 36 radial wires in all directions from its base for distances of 40 or more feet each (a total of 1500 feet of #14 copper wire). The radials are buried just below the surface.

I am getting good VSWR readings of 1.4:1 or less on all bands 80 - 10 Meters except for 17 Meters. There the VSWR is running about 2.5:1. It is just about all my built-in tuner can handle.

Has anyone encountered similar conditions such as this with only one band being way out of range? Any suggestions? I have doubled checked the installation procedure and looked for lose connections, etc.

> ...what Dr. Cohen is essentially saying is that if he draws a picture of of the Statue of Liberty and copyrights it, then his copyright applies to any picture that I might subsequently draw of the Statue of Liberty by claiming that mine is a derivitive work.<

Its worse than that, Jim. He's saying if he draws the picture, copyrights it, assigns the copyright to a company, then reporduces the picture in a journal as a scholarly work while failing to report notice of said copyright, he can still prevent anyone from ever drawing a likeness of that picture again--and sue them if they try. And, he can do this even if he didn't own the copyright when he sold the first publication rights in the first place! America's a great place, isn't it?

I asked the question about who "Minkowski" is/was and how that name came to be attributed to this family of shapes (including the zero iteration which is a square box), and Chip totally ignored the entire issue. He probably doesn't know --or doesn't want to tell.

But, here's the real kicker. If the MI2 is disallowed, then shouldn't all other iterations must be disallowed, too? This, of course, means anyone who draws even a simple square box (M10) or builds a square quad antenna must be equally in violation because this shape is graphically depicted along with the MI2 in the same article.

And, the question still remains. Is Minkowski a colleague of Mandlebrot, Caley, Sierpinski, or Cantor? Who is this myterious being and why is he so special? A little more scholarly attribution and a little less blustering bullpucky might be in order if credibility matters.

Why all this foolishness just because I disagree with you? I simply think you're wrong in some of your technical statements. There is no agenda beyond that on my part. Why can't you keep the discussion at that level? Disagree with me and explain in some detail why you think I am wrong, rather than huffing and puffing about Cushcraft and all the other unrelated issues. You know as well as I do that Cushcraft has no interest in any of this. We're talking about an HF loop antenna for heaven's sake.

BTW, I do intend to publish the work, I just need to pull it and all of the measurements together to make a comprehensive and definitive presentation.

If I took any of your statements above seriously, or if I thought anyone else did for that matter, you would have received a "letter" quite some time ago. As it is, the more you continue to rant, slander, harrass, and libel,

the more evidence you provide against your own position. In any event, your posts sure do provide a lot of entertainment. From my perspective, this whole issue and your posts are a big joke and I enjoy the laughs.

"Considerable amount of time" - 5 minutes

Yet another loop with similar or better performance. Random5.ez has been
sent to Roy for distribution at www.eznec.com at the FTP site.

Performance:

Frequency = 14.485 MHz
Resistance = 33.8 ohms
Gain = 1.87 dBi
2:1 bandwidth wrt 50 ohms = 1.58%

Reg Edwards wrote:
>
> Question about Bird power meters.
>

As a student I used to work for a government calibration lab that checked the calibration of Bird meters. They were specified to an accuracy of 5% of FSD. (Most were the Bird 43's). A site would send one in, with a selection of elements to have the calibration checked. We did not adjust them, only indicated pass/fail.

So few passed the +/- 5% of FSD spec, that many places sent them in with a note that +/- 10% of FSD would be considered acceptable.

I'm not able to recall every detail of the testing procedure, but know that power could be measured using a water caliometer. High power attenuators were available, which were calibrated (I'm not sure exactly how). However, meters were not tested using water calorimeters on a day-to day basis. It was too time consuming to check a meter of limited accuracy.

The day-to-day calibration of the meters used a transmitter, low pass filter, the Bird meter, a high power attenuator (plus possibly smaller ones) and a Marconi (or perhaps HP, I forget) low-power meter, measuring mW or possibly uW (I can't recall) exiting from the attenuators. The first high power attenuator was 30 dB. At some frequencies, a directional coupler and load was used instead of the attenuator. The attenuator or directional coupler and marconi power meter were all calibrated in house, ultimately against precision standards (water calorimeter etc.). A computer controlled the transmitter and read the data from the Marconi (or HP ??) power meter, while storing the calibration data for the attenuator or coupler.

While working at the lab, I purchased my own element to cover the 70 cm amateur band. I checked the new element at work, only to find it was not within spec, even when brand new. (The meter was not then new, but I had bought it new and never abused it). I returned the element to Aspen Electronics (the UK distributor) and it was calibrated at 432 MHz for me while I waited (I did not care too much for its accuracy outside the amateur band). I then returned it to work, to find that indeed it was then within spec at the spot frequency.

My one thought on these meters is that they are fine for tuning a TX up to maximum, but don't even consider them as precision instruments. They are not, nor will they ever be. Few meet the published spec after use, and while I can't say how many do when new, the only element I personally purchased was out of spec when new. Hence in my opinion, they are not really worth calibrating. They are undoutably, in amateur circles, a very over-rated piece of equipment. If you want to see if your amp is working they are good, but if you want to *measure*

power, with any degree of certainty, I would buy a used low-power meter, and somehow get someone to calibrate an attenuator for you using a calibrated spectrum analyser. That will give far better accuracy than a Bird ever will.

Traditionally, the antenna jack on a car radio has connected to the
top side of a tuned circuit, where impedance is quite high. The way
I visualize it, the shielded cable needs to be special because it
has low capacitance, so it won't mistune the tuned circuit by too
much. The trimmer capacitor that was in place in such radios
was to compensate for that additional capacitance across the tuned
circuit.

The antenna acts as a probe, to couple the signal into the receiver.
The concept is there in more recent "active antennas" where a short
whip antenna feeds a high impedance input stage, using a semiconductor
device rather than a tuned circuit to make that point high impedance.

One could theoretically have simply left the input coil unshielded,
but that causes problems in a car due to pick up of noise, and the
shielding that the car creates.

I gather this isn't the way it's done in more recent car radios.
You don't see the trimmer caps in more recent sets, and one Delco
I looded at fed the antenna jack to a low impedance point (i assume
a few turns of wire, but perhaps a tap) on a tuned circuit, which
feeds an RF stage.

The original concept may not have translated so well to transistorized
radios, since bipolar transistors have relatively low impedance input.

With loopsticks (or those old-style loops you'd see on the back of
older all-American Five's), the grid of a tube would connect to
the top of the loop. But when they translated to transistors,
the loopstick and capacitor would be isolated, with a coupling

loop of a small number of turns being used to get the signal
to the base of the transistor.

Those old-style loops probably came into use as radios became more
common, and nobody wanted to string up a wire in the backyard to
simply receive local stations. Since they needed a tuned circuit
at the front of the radio, it made sense to make it unshielded
to act as an antenna. When the switch to transistors were made,
it made sense to stay with the scheme. I have no idea when ferrite
loopsticks came into common use, with the coming of transistor
radios or before that. Probably the earliest transistor radios
were AM only, so there would be no incentive to switch to a whip
antenna at that point, and probably the loopstick remained even
when FM was added to such radios, because inertia is a strong
thing to break. Face it, an AM broadcast radio in most cases
is the same basic design that it was fifty years ago, with
the only change being transistors instead of tubes.

An excellent analysis except for one thing. It is not volts which has to be maximised into the first stage of the receiver -- but signal POWER.

Ferrite rod antennas are the most inefficient antennas imaginable. Receivers use the first Rx tuned circuit itself as the antenna. In comparison they appear to be extremely sensitive only because they are used to receive 50 KW MF local broadcast stations with an IF gain much greater than that of your HF amateur band receiver which is designed to be used with a 250 feet long dipole at a height of 60 feet.

The receiving aperture of a ferite rod antanna is no greater than a dipole about twice the length of the rod. It does have the advantage of being easily and low-loss matched into the base-emitter junction of the first stage, usually the frequency changer.

A short dipole antenna would need a large high-Q matching coil about the same size as the rod. So the rest of the story is self-explanatory.

The ordinary ferrite rod pocket receiving antenna is so inefficient it would burn out if used with only a 2 watt transmitter.

Whoa! You have stated that he is not a competitor as you do not manufacture amateur antennas. Now your saying he is Which is it? He shows you an antenna that is superior to the M12 and makes it available to all amateurs for perusal and you say no peer review. What gives? Your antenna models just fine in EZNEC, but his does not? What gives?

I can understand as you feel you have no peers, that peer review means something different to you than the rest of us. I for one am satisfied that Steve's antenna dos what he says it dos, and I consider myself his peer.

Your mental state is slipping by the day, we are all worried about you. Please seek competent mental help. I have genuine concerns about you being around young people in your present state.

I have written some software of my own to model Yagi antennas. It does not run on a Windows PC, but on a unix workstation (PC with linux is okay). See

http://www.medphys.ucl.ac.uk/~davek/ham/yagi/index.html

(Note the message on my web site about a bug in gcc's optimiser under linux, which means the programme must be compiled with the optimiser off under linux on a PC. This is not necessary on my Sun SPARCstation using gcc-2.85.2, nor was it on older versions of gcc on a PC).

I believe this software is as good as anything available, as the equations used are exact analytical ones - not polynomial approximations. The source code references the source of the equations.

What is apparent is that by adjusting the antenna for the highest forward gain, the input Z falls very low. One could design an antenna for quite high theoretical free space gain, but the input Z would be so low that losses would dominate (which I don't model).

In conclusion, design the antenna for a 12.5 Ohms feed impedance and use a 4:1 balun. Adjust the driven element length to make the impedance seen looking into it purely resistive.

Using 0.3 mm diameter wire (0.0003 lambda), at 300 MHz (free space lambda is 1 m), the following would seem reasonable, if designed for use with a 4:1 balun.

G= 7.15dBi, Z= 12.27+j 0.15 Ohms, SWR= 1.02:1 (in 12.5 Ohm system)

driven = 0.48086 lambda
reflector = 0.49414 lambda
reflector-director spaing = 0.09336 lambda

In contrast, a design for 50 Ohms (remember it is balanced, so use a 1:1 balun) input Z

G= 6.74dBi, Z= 38.78+j 1.67 Ohms, SWR= 1.29 (in 50 Ohm system).

reflector = 0.48887 lambda
driven = 0.47383 lambda
reflector-driven spacing = 0.19164 lambda.

(I personally prefer to design for 300 MHz = 1m, as it makes scaling nice and easy.).

If you give me the wire diameter, I could model it for you, or if you have access to a unix machine, download my source code and build the programmes yourself. I'm not sure of the exact band centre in the USA, but assuming it is exactly 20 m (I know it is not), you would need to scale all the dimensions by exactly 20. Hence the above would need a wire diameter of 6 mm, which is perhaps more than you wanted.

At 15 MHz (precise 20m in free space), the 12.5 Ohm design needs a spacing of 0.09336 lambda = 6.13 feet, so it fits your boom length.

My software can model the effect of random variations in the placement and lengths of the elements, but not a drooping.

Source record: 177847

David, thanks very much for the frank description of your experience with RF wattmeters. My own experience does not extend above 30 MHz and, insofar as precision measurements are concerned, 0.001 dB, only below 5 MHz. But I have no reason to doubt your findings by extrapolating my own experience to higher frequencies.

My interest is in measurements in general. I enquired about Bird meters only because they appear to be of the best US quality and from the frequency of being mentioned in this newsgroup a fairly large number of amateurs have practical experience of them. Whereas I have none.

It has been said (I forget by who) Radio is the most inexact of all the sciences. This is not surprising when one considers the propagation fade depths experienced at all frequencies. Perhaps it is the unpredictability inherent in radio propagation which amateurs have found so intriguing for the best part of 100 years.

Source record: 177849

Ian,
Since we're speaking of alternating current at RF frequencies,
the proper term is impedance. Except in specific instances, the
impedance that the radio 'sees' is almost never pure resistance.
There will almost always be some reactance of some kind present.
While I agree, the exact output impedance of a radio is seldom
50 ohms, it's close enough that the difference is unimportant.
It's certainly as 'exact' as the actual impedance of typical
coaxial cable.
'Doc

Klensir,
Just as a guess, I'd say that the dimensions for the 17 meter
portion of the vertical is incorrect. Re-adjusting the antenna
may correct the problem (it's probably going to 'screw-up' the
adjustments for the other bands, though).
Good luck....

Dr. David Kirkby, Ph.D. wrote:
"Hence in my opinion, they (Bird wattmeters) are not really worth calibrating. They are undoubtably, in amateur circles, a very over-rated piece of equipment."

Dr. Kirkby is too pessimistic. I spent over a quarter century with a company which operated over a thousand radios which all got regular checks with Bird wattmeters. Logs were kept which recorded the readings. Many different Birds were used and they agreed closely, short term, or long term, barring changes in the power measured. These measurements were repeatable and different meters agreed. Moreover the measurements were usually exactly what was expected and conformed to the specifications of the equipment being checked. Poor instruments don`t give consistently good results. All of the Bird wattmeters gave consistently good results, and were interchangeable. Dr. Kirkby`s experience is very different from mine. Since my experience is with dozens of Bird wattmeters making thousands of measurements, ever since 1960, and counting, I still use a Bird almost every day, I think Dr. Kirkby`s experience is atypical.

+ or -5% is not claimed as laboratory accuracy. But, compared to any other commonly available field measurement RF wattmeter, the Bird deserves the reputation it has with amateurs and professionals alike.

Best regards, Richard Harrison, KB5WZI

wouldn't it be better to solder on the wires, run them to a lithium battery holder and then just leave them in place? You could then just add the battery to the holder, replace the old battery and then remove the battery from the holder until next time. If there is enough room for this it would reduce wear and tear on the pcb and make the change next time much easier as there is less to remember 5 years down the road..

> 'Doc

Maybe I'm losing a grip on things Doc!

1. Why can't you have a 'resistance' at RF? Surely all transmitters are designed to work onto a resistive load - usually 50 ohms. I hope ALL my fantastic antenna systems present (via a transmatch, where necessary) a perfect resistive 50 ohms to the transmitter (my 'perfect' SWR meter indicates zero reflected power with my perfect 50 ohm load, so this must be true!).

2. Surely the output impedance of a transmitter should be considerably LOWER than the load which it is intended to feed. A power transmitter is NOT a lab signal generator. If the output impedance (resistance?) of a transmitter was equal to the load, a transmitter delivering 100W of power would dissapate at least 100W in its output stage. The efficiency could NEVER exceed 50% (and we have not added any other losses). You would have a pretty hot rig! How, then, does a Class-C PA have an efficiency of ~66%?

I have always understood that the output impedance of a transmitter is pretty low (compared with the design load), and pretty reactive (ie non-resistive). Have I been wrong? It won't be the first time!!.

Ian.

You'd better not. At the time I was wanting to review an AEA-CIA for RadCom, it was impossible to obtain one that didn't have serious glitches in the R-X measurement display. After trying two different models and a modification, all direct from the factory, I reluctantly gave up on it. The good points about the AEA-CIA were the superb build quality and it worked fine as a graphical SWR meter... but the magazine review was supposed to be about the new generation of R-X analyzers, and that feature of the AEA-CIA just wasn't reviewable.

Instead I reviewed an MFJ-269, and found it very satisfactory within the limitations of low-cost instrument. AEA, MFJ and Autek all share the same limitation of being broadband, and thus vulnerable to strong incoming signals when used with antennas. Build quality is adequate - almost everything is on machine-assembled SMD boards with a minimum of hand soldering.

That experience with the AEA-CIA was about two years ago. I have no knowledge about current production.

Hi Group,

Been working on a home project with data transmitter at 433 MHz.
My antenna is a PCB trace, 1/12 wavelength long and the osc is a colpitt with saw resonator.

My power goes down if I mount the PCB onto the metal siding of my garage.
The PCB is single sided.

Other than mount the PCB with stand offs, is there a way to prevent the unwanted coupling to the metal siding? Can I leave the copper on the other side of the RF circuit but ungrounded and then tune the osc? I would expect this to limit the unwanted coupling? Or maybe ground the copper side to the PCB RF ground point?

Thanks,

Paul

Jerry, no most hardline is not suitable for direct burial. I would
recommend placing in conduit. The conduit will both protect the cable,
and make it easier if you need to either replace the cable or add
another cable. I would plan well and use conduit large enough to
acomodate any future cable you may want to run out there. Try to
minimize the turns and use sweeps not short radius sweeps. I mostly
work with 75 ohm CATV hardline and we use flooded cable. The flooding
compund helps if you should happen to nick the jacket. If you should go
the direct bury route be carefule about your backfill. Rocks are a
definite negative. Good luck. 73, Bill

You might check the Icom list. There are several people there who might help you sort it out. AB4OJ, Adam Farson, is the resident Icom expert and he really knows his stuff. Also there have been some aftermarket RAM boards produced for some of the Icom rigs that cure the above problem, and work better than the original boards. One may work with the 745, and Adam will know. Also the Icom net meets on 20 meters SSB each Sunday afternoon, takes inquiries and offers advice. I don't have the time and frequency at hand, but if you subscribe to the Icom email list at QTH.net you can get them.
The 745 is one of the few Icom rigs I *haven't* owned.

Hello-

I have a couple of these things, but both have trouble reliably locking into the signal, maybe once every 3-5 days at best. I am located near San Francisco, CA., a hundred feet above sea level.

Can I get your thoughts about enhancing the antenna/signal level? I don't have bad noise here that I am aware of.

Maybe a Fractal for 60 KHz?

Thanks

I don't know of any comparative reviews, I'm not a big MFJ fan, but the only way you'll get my MFJ 259B is to pry it outta my cold, dead hands. My only squawks on the 259B being that it takes some work to figger out if the "j" is capacitive or inductive reactance, and it quits when R+j exceeds 600 ohms. But what do ya expect for a lousy $200?

Hi Kirby-

For what it's worth, I have a MFJ 259B and an Autek RF Analyst RF-1. I use the Autek only when carrying weight is an issue, otherwise the 259B gets 98% of the use here.

Kirby, you mentioned price range . . .

Consider spending a little more and get the AEA/Tempo CIA-HF analyzer.
It is much superior to the 259B. Please check the specs and compare
them. The enormous difference is that the CIA-HF plots curves of several
variables against frequency. That alone is worth the difference in cost
- you will see things in those plots that you so easily miss with
spot-frequency measurements. I won't even mention the relative accuracy
of the two instruments . . .

That would probably be easier than the one I came up with. I like the ability to switch easily. I didn't see that one before I gave the other example. Something is goofy with the news feed here. I'm getting most of the posts about 6 hours later. I usually get them real fast. I guess they changed something again. It crashed for a while the other day. MK

Well, you would be better off to find a few good books. But is some info around. You could try a search on yahoo or whatever. Also search the deja-news. Offhand I can think of one that almost surely has a some info on this antenna. I think there is an article on it. It's at http://www.cebik.com/radio.html I'm sure there are other places, but you'll have to search them out. I think you will get more detailed info from a book like one of the handbooks etc. Any of those cover those in detail. MK

Tom,
I would try this link (http://www.nerc.com/~jdegood/coaxtrap).
There is a traped dipole with an over all length of less the 60 ft to work
80-10 mtrs. It can be shortend and has the specs there to drop bands you dont
want or need. I have not tried it but the idea is sound.

They broadcast on 5, 10, 15 and 20 Mhz. You should be able to pick up
something. I have a cheapo Radio Shack wwv receiver that picks up wwv
in Ft. Collins just fine with a pullup whip antenna. You should be
getting either Ft. Collins or the Hawaii version of wwv unless you're
listening on something really wretched, altho' I can't thing of
anything more wretched than these little RShack gizmos, and they do
just fine :-)

Dear Old Wives,

One more time -

The output resistance, more accurately described as the internal resistance, can be anything it likes. To design the output circuit, tank or Pi-match or transformer turns ratio, no knowledge of that parameter is required.

More often than not the internal resistance looking back into the anode, plate, collector or drain, is some high value because the amplifying device can be considered as a current source. But who cares ?

PA efficiency is a function only of the operating angle of the device which is controlled by the grid, base or gate bias circuit. Plate dissipation, etc, is minimised simply by allowing current through the device to flow only when the voltage across it is at the lowest value of the RF cycle.

Small operating angle = high efficiency.

For maximum power output the resistive load which should be presented to the anode, plate, drain or collector is given by Ohm's Law as -

Load = (Peak Voltage Rating)/(Peak Current Rating) ohms.

Alternatively -

Load = K*(Square of DC supply voltage)/(Required RF power output) ohms.

None of these device ratings has anything to do with internal resistance.

And non-dissipative resistances are the invention of
baffle-gabs.

Sometimes I wonder if being cogent is a handicap. EXACTLY what contradiction do you see here? What does a non-existent transfer of rights to CQ Communications--the topic so described--have to do with a transfer to anyone else?

WHERE DOES IT SAY THAT I NEVER TRANSFERED COPYRIGHT--EVER?

WHERE??

All,
Please read this thread and tell me who has a problem with whom.
This guy has made it impossible for me to buy anything on the web, I've had to stop buying, as my wife and children have come to the conclusion that its too much a gamble.
How is it this guy gets favorable reports, did he threaten the people he screwed? As he did me? He threatened me, should I post this, yet he has the audacity to try to back out of his word by harrasing me.
The follwing is the thread of emails.
You be the judge.
In my opinion, this guy is a dangerous, unstable individual who needs to be dealt with through the legal process.
Any feedback, ideas on how to deal with him and this matter is appreciated.
He seems to believe he can and threaten people into submission.
Is there a type of syndicate on the web of people who procure for each other, thus having a vestid interest in falsly
recomending,falsly giving favorable comments on a trader for their own personal gain?
Lets see who comes out in his defense! There is a disturbing pattern
CAVEAT EMTOR!

If you want your money back Im sure we can come to an agreement, if you want another tuner...Im afraid, we cant...Because Im not going to buy another one......and Im not going to buy that one back, til Im assured that is in proper
condition like it was when it left.....that is the only option you have at this point...DO YOU UNDERSTAND THAT?...I could not..fail to pay you if I wanted to stay here doing what I do like I have for the past 6 years...do you understand that too?...So if you are afraid you wont get your money, arrange an escrow account and we will go thru the motions...you figure out how you wanna do it....If you talked to any real regular traders , they all told you the same thing...Murry does what he say and is a man of honor...Now lets hear you plan Jeff. If you have any contacts with KNOWN hamtraders, we will use them to go between if that helps your feeling...Ive paid more than 225 to watch a monkey fuck a football, but I ll be damned if I will do it for a weasel...73 Murray

After talking with several other ham traders last nite, we are of the opinion
that even though it makes no sense and is certainly petty on your part...the
best
I can do is take it back, if its in the same shape and whether it smells or
not,
refund your money....So I offer you this one time only opportunity...Send it
back
where it came from, insure it, pack it well...when it arrives I will refund
your
money. Anyfurther rhetoric from you will result in your continued ownership
of
said tuner....You wont have to worry about trading with me again Jeff, you
cant...I await your reply...my reputation is good, NO ONE and I mean NO ONE can
say Ive ripped em off, I will not send the money first, but I WILL send the
money and you know it...Ive paid more than 225 to to "See a monkey play
football",
its not a about money...73 Murray

The picture of W6RCA and daughters is cool, but I did not find info about the Icom. Could you please be more specific as to the battery information. I too have a 745 and it is starting to jump frequency on me (about 3 kHz up for about 30 seconds, then back again). Perhaps the problem is the battery you are referring to.

Thank you.
Al

This is a reference to the TV show starring Dianne Carroll (surely I spelled that wrong), about the only notable thing relative to it, is that it was the first network series that starred a black female.

Uhhh...he seems to be talking about the 60 Khz wwvb signal, not wwv on 2.5,
5, 10 Mhz.

Totally different ballgame.

Hi Al, the battery needs to be replaced every 5-10 years. Sorry, I
sold my 745 and don't have the manuals anymore so that's about all
I remember.

Your problem doesn't sound like a battery problem to me. It sounds
like the PLL is coming unlocked every so often and the problem
will probably gradually get worse. I had a similiar problem with
my 725 which was fixed by readjusting the lock range on the PLL.

1130. Higher power in new vehicle?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-26 14:05:20 UTC
From: Scott <yetbbwa@grove.iup.edu>
Message-ID: <39F83A20.F6E6BE9D@grove.iup.edu>
Source record: 177626
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.antenna

No, my new vehicle isn't possessed!

I wanted to up the power in my HF Mobil setup in my truck. Is there any danger of running 500 or more watts in a new (2001)Chevy 1500 Truck? I have heard some bad things about running power in newer vehicles - does anyone have any insight/advice? I would being using 40 meters on up. Any bands cause more problems than others?

Scott.

Not seeing any posts last night and early this morning, I expected this would all just fade away.

Does anybody recall this statement by NC:

>
>> What Mr. Best has done is produced a end-loaded meander model which,
>> unfortunately, does not work in practice as the model suggests--this
>because
>> NEC4 is incapable of modeling close-spaced meanders of small size and
very
>> close spacing.
>>

NC's talking about the random2 and random3 designs that were posted by Roy. He clearly claims that my design will "not work in practice".

Well, for the record, I constructed the MI2 loop, one of my arbitrary loop designs (random4) and one of the meander line designs (random3). I chose an aperture size for the MI2 loop such that I expected it to resonate at 300 MHz. It actually resonated at about 298 MHz. The resonance of the random4 design was at about 301 MHz. Anyway, the random4 design had a higher resonant resistance than the MI2 by about 20% (no numbers will be posted here) which is consistent with the EZNEC model predictions. Looking at the random3 meander line loop (the "not work in practice" design), it resonated at about 350 MHz rather than near 300 MHz. Resonant frequency of the meander design may be tough to model as it is a sensitive parameter. Change the wire diameter in any of the modeled antennas and resonant frequency shifts consierably. What was really interesting, however, is that the meander line resonant resistance was about 50% higher than that of the MI2 as EZNEC predicted. All antennas have current and voltage max's where the

model's predicted and radiated quite well.

As for "Mr. Best's manuscript", it's in preparation for a conference submittal deadline of November 17th.

Steve, VE9SRB

A dipole is very easy to make and put up, especially for 10 and 20
meters. You can use two, fed with the same coax, one for each band.
Something to think about is the new regs regarding RF exposure when
using antennas inside the house. Do some calculations to see if you
are OK. An antenna in the hallway would be especially bad, unless you
are running very low power.

Take a look at http://www.ameritech.net/users/willco788/my1.htm . They
make a replacement memory board for your radio that, besides not
losing data for the CPU (it will lose memories you have programmed in)
when the battery goes dead, it gives you up to 1,024 memories. It is
a little pricey at $135, but if you don't want to spend that kind of
money, I think they will also program your card for less than Icom
wants. Icom may no longer even do it. BTW, I put one of the Willco
boards in my IC-745 and it works great.

I've got a GMC1500. When I tune my HS1600 on 40m, the speedometer
goes full scale past 100 mph. This is with only 100w and a rear
bumper mount. Only seems to happen on 40m. I haven't gotten my
SGC-500 installed yet but I plan to avoid 40m with 500w.

I receive WWVB very reliably here in the mountains of western North Carolina, but found that selectivity is the key. I use a tuned 100 turn loop on a 24 inch bicycle wheel, a design I found here on the Internet. That feeds a balanced pair of 40 dB gain instrumentation amplifiers made up from LM833 op-amps and results in a very high level of signal strength from the loop. (WWVB is about -70 dBm out of the amplifiers) The tuned loop is hung from a nail in a basement workshop, not a very good location.

I had quite a bit of trouble with that arrangement feeding a TRF receiver while feeding a HP-312 selective voltmeter was a piece of cake. After quite a bit of investigation, I found that the computer monitor in the hamshack 2 floors removed was putting in a +10 dBm signal on 58.5 KHz out of the loop amplifier, this despite a good bit of selectivity in the tuned loop itself. Since the frequency conversion of the 312 did me in trying to use the signal to a comparator, the only way I could get the TRF to lock up was with a sharp filter at 60 KHz proper. It no longer matters what's on or off at my home, or my neighbors for that matter, I can maintain lock 24 hours a day now although the grayline makes it unuseable for a few hours each day.

Good luck

Sorry, Jeff, but I have to agree with Murry on this one. It looks to me like he made every reasonable effort to work with you where he could (a refund, a trade for another unit if he could find one, mediation, etc.). In reality, I think you're being a little absurd to have such high requirements on a used item (never owned by a smoker??). If you want something like that, then you should buy new since it is almost impossible to know the entire history of every used item a person might come across.

At this point, I think you should apologize to Murry, send the unit back to him (assuming you've not messed it up), and get a refund. That is assuming that he is even willing to continue dealing with you (at this point, I would probably tell you where to go and walk away - no refund, no nothing).

You posted a message in this newsgroup asking for opinions and I gave that opinion. And with that I'm out of this. I have no desire to argue with you, or get in the middle of a dispute between to two of you.

My experience is that either work well and deliver comparable signal to noise ratios on MF as long as they well engineered.

> Bart may not have included the enormous loss in coupling an antenna so
> short in terms of wavelength. All signal transfer schemes will prove
> very lossy in the usual receiver. The monopole will be a high capacitive
> reactance in series with a tiny radiation resistance. Not easy to couple
> efficiently into a receiver.

The losses were taken into account by considering the loaded Q of the tuned circuit which includes the antenna. I assumed the objective was to deliver the largest possible signal voltage to a high impedance, voltage noise limited, amplifying device. Typically this would be the objective for a MF broadcast receiver.

The primary objective of a receiving system is to provide an adequate demodulated signal to noise ratio to the user. The maximum signal to noise ratio is not necessarily achieved by delivering the maximum power from the antenna to the first amplifying device. Optimization of signal to noise ratio is a complex topic involving a number of practical tradeoffs.

Hi Tom, My reply to your email was bounced back, here's my general reply to the group. I thought all in the group could be helped by this advice.

Regards, Lou N2JPR

Hello Tom,

My name is Lou, callsign N2JPR. Unfortunately, I had the same situation twice in my life, a condo and an upstairs apartment, both with attics. My nightmare has been over for years. My advice is as follows:

1. The only, and ultimate, solution is to permenantly move to your own house on a minimum 1/2 acre wooded plot. There, you can play "antenna" and put out KW level signals until your hearts content without bothering neighbors, etc.

2. If you choose to mount "anything" in this attic, it will definitely interfere with all the usual electronic junk (cordless and hardwired phones, digital appliances [TVs, VCRs, Stereos, etc.] alarms [including smoke], etc., etc.) at anything greater than 10 watts. Your neighbors (or in some cases, your WIFE) WILL find you out and at the very least report you to the condo association who will threaten to evict you (DIVORCE in some cases) if you don't stay off the air. If you now become a QRP'r at 5 watts or less you should have no problem interfering with others at those close antenna-electronic junk distances.

3. Now comes the NEW problem. Your attic antenna, compared to a REAL outdoor antenna (dipole, beam, vertical, etc.) really SUCKS. So, between your inefficient antenna system and your 5 watts of power, your destined to become one of 2 things:

a. A super-frustrated ham operator, in good standing with your condo association (in some cases WIFE) with no signal, no QSOs and no QSL cards (DX will soon become a fantasy).

b. A very happy shortwave listener until the day you bite the bullet and buy your own piece of land.

Two-cents from a happy ham, now on solid ground with antennae and signals galore.

73, Lou N2JPR

Hey,
looking at a design at
http://home.t-online.de/home/dl5neg/23cm_ant/23cm_ant.htm
I get the feeling something this compact would suite my needs great,
altough I would like
to stack 2 or even 4 of theese, so what would be the best way to do
this?
This is only for reception and not transmission, I would really like to
use 75ohm low-loss
coax witch I have alot of here, instead of expensive RG-8 or similar.
Any suggestions?

Regards
//Ash

Just bought one of these at the local Sam's Club for $21.95 - mine
says it updates at 0055 Eastern standard- this will be 3 hours earlier
on the coast. If yours is the same, it should try every 3 hours if it
cannot find a signal. Perhaps a # 30 wire looped in the attic feeding
past the clock with a couple of turns looped in the rear of the clock
will supply more signal. Could be a fluorescent light or a dimmer
causing noise also. These use a loopstick antenna which may be in a
null. Try a 90 degree wall.
Wish I could find a way to set mine to UTC but it only recognizes
Eastern, Central, Mountain and Pacific with a daylight savings
selector.

Thanks for the advice guys! I am thinking maybe the best thing to do (short of buying one of those Isoloop things) would be to build a dipole as long as possible and just run it through my tuner. I am also figuring that I should also keep the power fairly low since I am sure if I put out a full 100 watts, I'll be heard through all the neighbor's TVs, toasters, phones and causing ripples in their toilets! :-)

I'll check out those web pages some of you mentioned and see what I can figure out from there.

Failing someone coming forth with one, you might just get a length of
PVC or ABS pipe to use as a shipping tube. Neither is terribly
expensive, and can be outfitted with a screw-plug end.

Cheers,
Tom

HAMFEST October 29, 2000 - Lindenhurst, LI

GREAT SOUTH BAY AMATEUR RADIO CLUB
ARRL APPROVED LONG ISLAND HAMFEST - October 29, 2000

LINDENHURST, LI - NY

On October 29, 2000 the Great South Bay Amateur Radio Club will again sponsor an indoor Hamfest-Computer Show. The location will be at the:

Knights of Columbus
400 South Broadway, Lindenhurst, NY.
This is an ARRL approved Hamfest.

There will be radio equipment, electronic components, computers and accessories, software, books, technical manuals, ARRL information, Amateur Radio License Exams, Door Prizes.

Advanced registration is $15.00 each table. Tables at the door are $20.00 each. Contact Walter Wenzel KA2RGI at 631 957-0218 for table reservations. NO TABLES WILL BE RESERVED WITHOUT PRIOR PAYMENT due to the space available.

General admission is $ 6.00. Wife's and children under 12 admitted with no charge.

VE - ARRL - 12:00 NOON at Babylon Town Hall, 200 E Sunrise Hwy, Lindenhurst. For exam candidates please remember to bring your original FCC Amateur Radio license (if licensed), any C.S.C.E. forms that are pending, plus a photocopy of each, pens, calculator, formal form of ID (preferably photo ID),
and the examination fee, to the exam session. Current ARRL/VEC fee is $ 6.65,
exact change is appreciated.

Talk-in will be via GSBARC Repeater on 146.685 -600 136.5 PL.

Food Service during the Hamfest will be provided by members of the Knights of Columbus Council.

Information is also available during the GSBARC 2 meter info net every Monday evening at 7:00 PM following the Newsline Report on the W2GSB repeater, 146.685 -600 136.5 PL required. You may also write to:

Source record: 177649

Like the other poster, I don't think your problem is the battery.
I don't know for sure.

However, since you asked, here's some info about the battery.

There is a small board inside the 745 that plugs in and is also held
in place by 1 screw, if memory serves me. The board is easily
accessible by removing the top cover, and easily identifiable by
the size, and the fact that it hosts a lithium coin cell.

That board contains the memory (RAM memory) of the stuff you
store *plus* the stuff ICOM stored in there - the "brains" of the
rig. The stuff ICOM stored allows your radio to work. I have heard
that if that "stuff" is wiped out (due to battery failure) the radio
becomes a vegatable. Ok - that board has a 3 V lithium coin cell
soldered on. It is that battery that needs to be replaced before it
runs down. The replacement procedure requires providing 3 volts
to the board while you are unsoldering the old battery and soldering
in the new one.

What I do (I've replaced the battery twice) after removing the board
from the rig is as follows:
1) solder a couple of wires to the board before removing the battery;
2) run those wires to a brand new 3 V lithium cell;
3) unsolder the old battery;
4) solder in a second brand new lithium cell;
5) unsolder the wires installed in setp 1;
6) reinstall the board.

You need 2 new lithium batteries, some wire and about
ten minutes from start to finish. The first time you do it,
take an hour and be 100% sure of each move before you
make it. You need to solder those wires to the board such
that you can remove the old battery and still keep 3 V going
to the board - selecting the places on the board where you
will add the wires is both an electrical (so you get the polarity
right) and mechanical (so you leave yourself plenty of room
to unsolder the old battery without disturbing the "life support"
attachement of those 2 wires) consideration.

TDMA and CDMA are cellular standards
TDMA Time Division/Demand Multiple Access
CDMA Code Division Multiple Access

AT&T uses tdma for their cel service and bellatlantic/verizon and sprint use cdma.

basically I am suffering because my cel phone does not work at work, the place that I spend most of the day. Since the phone company could care less I have to find someway to boost or amplify their cdma/tdma signal.

thanks

Hi OM,

Odd how one can claim TRUTH, and OBEYING LAWS after having made fraudulent statements about technical issues that were "protected" by a patent pending. In TRUTH they were not. The simple fact of the matter is that these fraudulent statements were made intentionally as the patent process is one of full disclosure and the applicant is never surprised by what is issued. There are exceptions for idiot savants I suppose.

The same source also insisted that their login/account name was a registered trademark that we all had to identify as such. The same source is also ignorant of the fact that the enumeration of data is not protected by copyright. Let's see, topics range through Trade Secret, Patent, Trade Mark, Copyright - and everyone of these issues has been distorted or so thoroughly confused as to diminish any sense of intelligence. It is not unusual that this source also recommends the services of a lawyer (and by all appearances has no such aid for themselves).

But as the ethics of this source are so prostituted to ego, such issues as TRUTH and OBEYING LAWS are remote considerations serving only as wobbly crutches for a crippled logic.

#1 Topic of the antenna community:
DO NOT RESPOND TO TROLLS OR FRAUDS

Reg Edwards, G4FGQ wrote:
"And non-dissipative resistances are the invention of baffle-gabs."

A Class-C amplifier delivers no power into a short or open circuit. Experimenters have demonstrated a real impedance exists which extracts maximum power from the amplifier. The amplifier may not last long at maximum power output if it can even get there, but it is shown that the maximum power transfer theorem prevails.

The tank circuit makes the voltage across itself sinusoidal through its balanced reactances. This resulting sinusoidal voltage produces a sinusoidal current in the load resistance

The load resistance at maximum power transfer matches the internal resistance of the source.

Reg is right that it has nothing to do with plate or collector resistance. If these published values were in series with the source, there would be next to no voltage across the load.

The internal resistance has to do with how long the devices are switched off as a part of the electrical cycle, plus the unavoidable loss in the output circuit.

Entirely different are the "baffle-gabs" of "Zo" and the "377 ohms" of free space. But, these don`t dissipate either.

Best regards, Richard Harrison, KB5WZI

Some vehicles don't have sufficient shielding around their electronics when it comes to higher powered RF. What happens is one keys up on the radio and the computer which controls the engine gets RF overloaded, and as a result, the engine shuts off. I've heard that some 1980's Toyotas definently had this problem.

Some CATV cables have the braid impregnated with a compound that prevents
water migration
through the length of the coaxial cable. A small slit or cut that would
normally allow water to wick
into to the braid if the braid wasn't flooded with this compound during
manufacture. You'll recognize
this type of cable if you ever see it, the braid looks like it was dipped
in ScotchKote or something similar.

I have a friend who transmits with about 100 watts on 10 meters
sometimes and it will occasionally kill his 1980 Toyota Supra (EFI
I-6). But that is an old car too and the wiring is a rats nest as you
might expect. On my 1986 F-250 diesel truck the tach (electronic
reluctance pick up) drops to zero sometimes while transmitting on a
450-some odd MHz commercial channel with an HT, but on no other
frequency that I am aware of.

I would assume, (hope) that you could ramp up the power and if it
doesn't kill the engine or cause weird problems you would be safe. That
is my way of doing things. And then there is QST's mantra, namely,
"install six RF chokes over everything, 3 times over."

1164. Re: 50 or 75 ohm ?

Newsgroup: rec.radio.amateur.antenna

Cam - how do you know?
It would be a litle difficult to measure. I'd say, find two dummy loads of different resistances, say 50 and 75 ohm, measure the resistances and measure the (relative) RF
voltages, and you could calculate the output impedance of the rig.
As to what that should be - for a small Tx of a few watts, the output matching is designed for a 50ohm match to get max pwr, meaning that the same amount of RF power is dissipated in the power amplifier - that's no problem, and I've done this on an old CB set and found it to be 50ohm. For a professional Tx of some hundresd of kW, it makes sense to match for best efficiency, (and you certainly wouldn't want to conjugate match a power station to its load!) But, I wouldn't like to predict what it would be for your IC-706. Does it vary with power setting? Let me know when you've tried it. Regards - Jules

The permanent modification you suggest would be better, if
it could be done. My recollection of the way things look in
there is that there isn't enough room on the board to do it that
way easily. But I did not spend any time investigating it either
time I replaced the battery, so it may be possible.

KB9WFK@mindspring.com wrote:

>WHERE DOES IT SAY THAT I NEVER TRANSFERED COPYRIGHT--EVER?<

Hmmm--you said you DID trasfer the copyright to FAS in 1995 and only got it back last week! Does anyone else have reason to think you did otherwise? I don't.

.

>What does a non-existent transfer of rights to CQ Communications--the topic so described--have to do with a transfer to anyone else?<

You delivered a manuscript to a journal with a promise of first North American publication rights. Your manuscript would not have been accepted without that promise. Moreover, you were (eventually) paid for your contracted services. Are you denying this transaction ever took place?

If the transfer of First American publication rights was a "nonexistant exchange", than it was "nonexistant" on your part only.

If I were you, I wouldn't admit that on a public forum because it could only mean you provided the material for compensation under false pretense because it didn't belong to you. The obligation and expectation that you controlled this material was surely there. But, you say you collected that money for something "nonexistant"--and you may be right. If FAS owned the copyright, they were the only entity entitled to release the meterial to a magazine--and the only entity entitled to receive compensation for it. Unless, of course, they gave you express consent to publish their material--which it would have been unethical not to report. It was not reported.

Are we talking cogency or voracity? The meanings are very different, but often confused.

I suspect you're out of luck. Most cell comms are line of sight, an amp is not gonna raise your antenna height. Plus telephones are duplex devices, how would you switch between "send" and "receive" with just an amp?

I have the Oregon Scientific Time Machine model and it has
worked flawlessly for several years.
It initially took a while for it to update though.
At first I had my antenna laying on the floor and it refused to update.
Moving the detached antenna up off the floor onto the rear of the
nightstand with velcro cured the problem.
The model I have also has a signal stength indicator for optimizing
the reception.
This is the only clock in my house(besides my Heathkit GC-1000)
that I don't have to bother with when the daylight savings time change
occurs.
Now if they were only all that way...!!

On another note check the website out below.
Lots of information there on WWVB in Colorado.
Nice pictures too !

The bigger problem with 90s vehicles might be the ampacity of the
increasingly
lame batteries and alternators. With a 100w xcvr and a 500w out amp you
have
to be pulling 75-80 amps key down. Assuming a 50% duty cycle even 35
amps
average might fry something, never mind the lousy voltage regulation.

My opinion: you are wrong to post this, which appears to be an
attempt to discredit (to say the least) someone you bought something
from over the internet.

As to the facts you present: my opinion - you were wrong to expect or
demand any sort of change in the deal you agreed to, based on a slight
odor. Nevertheless, he did make several avenues open to you to pursue.

Like the other respondent, I've no wish to get into the middle of this -
just answering your request for others' opinions.

This is almost certainly because it turns down the power when the load
is not 50 ohms. I doubt if it is connected with the concept of 'max
power out when the load equals the source impedance'.

Is the output impedance of your audio HI-FI amplifier equal to the
impedance of the speakers (eg 8 ohms)? No. It is ~ zero.

Is the output impedance of your car battery equal to the combined load
impedance of the lightbulbs? No. It is ~ zero.

Is the output impedance of your mains electrical supply equal to the
load of your electrical system? No. It is ~ zero.

Is the output impedance of your transmitter equal to the load of your
antenna feedpoint (ie 50 ohms)? ....

Ian.

OK, good. I was conjuring up visions of somebody pumping some kind of goo into
an underground PVC coax conduit. Understood. Tnx.

Source record: 177680

The output impedance of the audio hi-fi is not zero. It will be specified for the speaker impedance it is made for just as your transmitter is. The output circuit is designed using similar methods.

The car battery impedance is not zero. It does have an internal impedance. It is related to the voltage under load and the maximum current it can put out. If batteries were not this way then a flashlight battery could put out the same ammount of current , just for a shorter duration. There is a definate load where the battery will supply the maximum ammount of power to a load. Batteries are thought of as a perfect power source with a series resistor equal to the impedance of them. If you can do the calculations then you will see how it will take a certain load resistance to get the most power out of a given battery. Not the total over a period of time, but the maximum ammount in a surge.

The AC mains are the same way, they just hapen to have a very low impedance, almost equal to zero. You will loose alot of power in the wiring compaired to the ammount they can supply. That usually explains why the lights dim when a big moter starts up.

Now, here's a thought. How about we all migrate over to the CB newsgroups and tell them what a great piece of work the fractal antenna is -- we could all praise the fractal, recommend that they all get themselves one. You know how the CBers are -- they'll flock to the fractal as The Latest Thing (excuse me, in CB lingo that would be "Th' Latest Thang").

This would be beneficial because, as the fractal antenna becomes the standard on 11 meters, none of them would get any RF out of their own backyards, thereby silencing the whole crowd.

If it delivers its maximum available power into a 50 ohm load, isn't
that a conjugate match by definition? :-)

> It would be a litle difficult to measure.

I have a bunch of 600 ohm 50w non-inductive resistors removed from old military SWR meters and I have paralleled 8, 12, and 16 of them. The power output of my IC-706 is greatest at 50 ohms. Until 12 watts reflected power is reached, the IC-706 obeys the following rule: Forward power equals 100 watts minus reflected power. The power output of the PA is reduced by the magnitude of the reflected power until 12 watts reflected is reached. After that, the power output of the PA is reduced to maintain a constant 12 watts reflected. ICOM obviously detects reflected power internally using a 50 ohm circuit.

So the question is: Since the IC-706 outputs its maximum available power only into a 50 ohm load, is it by definition, conjugately matched at 50 ohms? :-)

That's not a bad idea if there's enough room. When I replaced the
battery in my IC-271 (same battery) I used those tiny clip leads with
the wire hook at the end to attach to the battery circuit at the
easiest point. I used a second battery to power the circuit and
unsoldered and replaced the existing battery. Was fairly easy to do,
but wish I had thought of your idea. Of course I have solved the
problem in my IC-745 with the Willco board. BTW, the battery in the
IC-745 was still going at 15 years. Lucky I suppose.

I would suggest you be VERY careful modelling a fractal design in EZNEC and comparing it with an arbitary shape design.

As we know EZNEC splits the antenna up into segments. As soon as you do this you are giving your random design structure and I would expect it to be modeled more as if it were fractal shape (well, that is if you call the 10m antenna on frac's site a fractal shape - personally I would argue that is is not truely fractal - or fractal to three levels only)

It does say something that your model of the frac design performed as he claimed his practical version did, however.

It really goes against a lot of other posts I have seen. The real question is "what is a fractal shape" and how many times the basic unit has to be repeated inside itself to be classed a "fractal antenna".

Given that there has only been personal attacks to try to discredit this design and your modelling agrees with the designers specs I am considering building one. I don't yet have an antenna for 6m so you like to get the design (i.e. the length of one edge of the outside box) for it for 52MHz.

Perhaps I could just scale it to be about 60% smaller? That would make it abot 3 feet square - not a bad size 6m antenna.

I don't quite follow this. Are you saying that EZNEC analyzes any
antenna as though it were a fractal, or that it will convert any antenna
into a fractal form for calculation?

High quality lab signal generators use feedback to improve source match, ie, maintain a 50 ohm output impedance. In the bad old days, it was common to install a directional coupler and diode detector in a test setup and feed the detected signal back into the "leveling" input on the generator. Often the detector was placed some distance from the generator output spigot.

I think we should put the alc detector at the antenna and we wouldn't have to worry about swr any more. Just turn up the wick until you get 1500 W at the antenna and call CQ DX.

Also, (and this isn't just in response to Cecil's post but a general comment on this thread) there are high power amplifiers designed for antenna and susceptibility testing that put out 1KW+ and are true 50 ohm output devices. They use distributed amplifier techniques to achieve excellent linearity, wide instantaneous bandwidth, good source match and they tolerate running into open or short circuits. Efficiency is poor, but what the hey, we're rated on output power these days so who cares:))

Just line up a dozen 8877's and have at it.

73,

Wes

Fortunately it is NOT a conjugate match delivering maximum
available power into 50 ohms. Japanese designers have more
sense.

Cecil, just a suggestion, go ahead and vary the load for
maximum output with maximum available PA drive, with ALC
disabled, and report your results on this newsgroup. ;o)

There may be a word missing in that paragraph -- is that 3-4 dB/mile? On HF, it certainly can't be 3-4 dB/tree. :-)

Too, this would be for propagation between two stations located on the ground -- direct or ground wave. The typical HF antenna located in the trees would be launching energy skyward for most paths, passing through about 0.002 mile of tree, typically.

I agree and have said the same in the past. He seems like a bright guy
but his childish behavior sort of negates any credibility. He may very
well have made a huge breakthrough in antennas, but I'll never know
because I'm not one to judge, I know relatively little compare to the
others here, but it's the behavior and constant arguing that sends up a
big red flag. He just does things that lack good judgement.

John--

The very first fractal antenna article shows a 6M MI2, in 1995.

I would be happy to send you the MI2 file EZNEC for 6M, so that you can build and see the impedance is very close to 50 ohms. The file is copyright and can only be used as a personal one under "fair use", and not published or distributed elsewhere.

Drop me e-mail and I will send it out.

Chuck O'Neal has modified the above post to make it exactly the opposite of what I said.

Here's what I said:

"You are a sick fellow. I am a married monoganmous heterosexual. The date is for
the 10M Contest."

I still feel you are a sick fellow Chuck.

I have colleagues who have died of AIDS. It is a horrible death and tragic for all who know those who die in this untimely way, and for those who love and cherish their friendship and talents.

I miss them.

I do not have AIDS Chuck. Also, I am not gay and I am not fat.

Hi John:

I don't quite follow your statements regarding EZNEC modeling a "random" shape as a Fractal. Perhaps the word "random" is a bit ambiguous. "Arbitrary" is clearly a better choice of wording. The only point in the comparisons is that taking the same total length of wire as in the MI2 and rearranging it into a non-fractal shape within the same physical aperture, you will get similar or in some cases better performance. The only constraint that I maintain in the arbitrary arrangement is keeping the shape symmetrical. Although Fractal loop antennas are always symmetrical, all symmetrical loop antennas are not Fractals. This distinction needs to be recognized in the discussion.

Peter is correct,CATV hardline designed for underground use also has
the sticky stuff. Wicking is less of an issue with hardline, but
corrosion of the aluminum shield is still a concern. Especially in
alkaline soils, the aluminum can become a white powder is in short
order.

Ed Hare, W1RFI wrote:
"---is that 3-4 dB/mile?"

Good question.

The quotation is from the War Department`s engineering manual. I think the authors were measuring loss between two points on the ground within line of sight distance. The military used frequencies between 20 MHz and 100 MHz for vehicular communications in WW-2. Old timers will remember the "tank sets" with chromium push-buttons, etc.. We used the same radios aboard our navy ship to communicate with other ships in convoy, and tanks on shore, or on our tank deck. We didn`t consider FM communications at VHF a violation of radio silence except when the times were considered perilous, like dawn, dusk and night.

What is missing from the War Department data is the distance between measurement sites. The authors probably wanted to give a feel for the problem without being held responsible for exact numbers. There is wide variation in foliage and density. Terrain variations could obviate the foliage problem. Radio users could be on opposite sides of a valley or on opposite sides of a mountain.

The data show that lower frequencies are less affected by foliage than higher frequencies. Also, horizontally polarized waves are less affected than vertically polarized waves as would be expected, unless tree growth were primarily horizontal instead of vertical.

From the trend of the measurements, I think trees are of little concern if you are using horizontally polarized sky-waves for short and medium distances, and not too serious a problem at low elevation angles for great distances.

Best regards, Richard Harrison, KB5WZI

Hi Tom, My reply to your email was bounced back, here's my general reply to the group. I thought all in the group could be helped by this advice.

Regards, Lou N2JPR

Hello Tom,

My name is Lou, callsign N2JPR. Unfortunately, I had the same situation twice in my life, a condo and an upstairs apartment, both with attics. My nightmare has been over for years. My advice is as follows:

1. The only, and ultimate, solution is to permenantly move to your own house on a minimum 1/2 acre wooded plot. There, you can play "antenna" and put out KW level signals until your hearts content without bothering neighbors, etc.

2. If you choose to mount "anything" in this attic, it will definitely interfere with all the usual electronic junk (cordless and hardwired phones, digital appliances [TVs, VCRs, Stereos, etc.] alarms [including smoke], etc., etc.) at anything greater than 10 watts. Your neighbors (or in some cases, your WIFE) WILL find you out and at the very least report you to the condo association who will threaten to evict you (DIVORCE in some cases) if you don't stay off the air. If you now become a QRP'r at 5 watts or less you should have no problem interfering with others at those close antenna-electronic junk distances.

3. Now comes the NEW problem. Your attic antenna, compared to a REAL outdoor antenna (dipole, beam, vertical, etc.) really SUCKS. So, between your inefficient antenna system and your 5 watts of power, your destined to become one of 2 things:

a. A super-frustrated ham operator, in good standing with your condo association (in some cases WIFE) with no signal, no QSOs and no QSL cards (DX will soon become a fantasy).

b. A very happy shortwave listener until the day you bite the bullet and buy your own piece of land.

Two-cents from a happy ham, now on solid ground with antennae and signals galore.

73, Lou N2JPR

Easy to determine their internal impedance?
Divide the open circuit voltage by the short circuit current.

But he certainly does the rest of us a great service in that he reveals his calibre exactly for all the world to see in cyrstal clear detail. As an appendage to that display, he also reveals the truth about his Fractal nonsense, which is to say that there is NO truth to any claim of the superiority of any design based on fractal shapes. They just LOOK differnt, and it sure appears that his scam is based on that fact plus references to others' writings which prove no such nonsense. Steve's analysis finished dispelling that myth. Now all he can do is whine abouit how "wrong" Steve is, still without support whatever, only those vague references to others obscure writings which do NOT support his conslusions. Blaaaaaaashhhhhh..

I wrote:
"There is wide variation in foliage and density."

Of course, there is seasonal variation. An afterthought is that generals refight the last war. The military schemers probably emphasized Europe in their tree thoughts. Forests in Europe tend to be swept clean of underbrush. The practice is to gather everything for fuel and other uses. Even the lower branches are plucked.

A relatively clean wooded area was probably used for the War Department`s tests of foliage attenuation. Attenuation from trees outside Europe is probably worse. Just speculation.

Best regards, Richard Harrison, KB5WZI

Don't be too discouraged. I ran with a 20 M dipole in my attic for quite a while and it worked reasonably well (down an S unit or two from the one I have now at 40 feet (outside, of course). It is a bit noisier that being outside (I've got dimmers on practically every light, and these are mostly recessed in the ceiling below).

You don't need a kilowatt. 100 or 200 gets me through even thereally tough pileups. Read the Oct QST article on the difference between different power levels.

Consider an Alpha-Delta DX-CC and "trim off" the 80/40 meter portion (it's longer than you have room for) - and you'll have 20, 15, 12 and 10M.

You should do fine. Just remember to do your RF eval

I put eye-hooks into the ridge beam and suspended the wire from that so it was as high as possible.

I'll take that luggage in Samsonite, please....

A rat done bit my sister Nell

With whitey on the moon

Her face and arms began to swell

And whitey's on the moon

I can't pay no doctor bills

And whitey's on the moon

Ten years from now, I'll be payin' still

While whitey's on the moon

You know, the man just upped my rent last night

'Cos whitey's on the moon

No hot water, no toilets, no lights

But whitey's on the moon

I wonder why he's uppin' me

'Cos whitey's on the moon?

Well, I was already givin' him fifty a week

And now whitey's on the moon

Taxes takin' my whole damn check

The junkies make me a nervous wreck

The price of food is goin' up

And as if all that crap wasn't enough

A rat done bit my sister Nell

With whitey on the moon ...

Yeah, didn't Harry Truman show real intestinal fortitude when he did that? What if Hitler'd had that technology? Your dear old Iles would still be red hot and unihabitable. Of course, illiterates like you can't see what Truman saw clearly- that it was either a large number of them, or a large number of us that had to go, in settling the issue. He clearly saw that the best, cheapest way - for *both* sides- to settle it was to do exactly what he did. Pleasant it was not. Very applicable it was indeed.
I can't help wondering where the brainpower is centered in the Isles- can't you people understand that the best way to change the mind of warlords and their committed followers is to simply give them far more of their favorite subject than they could ever want? Quickly and decisively? That was probably the ONLY way to ever change the Japanese mindset and change it quickly and permanently. Anything less would have served only to stiffen their resolve, prolonging the conflict with far greater numbers of casualties on both sides.

> Still brooding around trying to prove what "real men" you are.

Here in the Colonies we oh so often in the past century have had reason to wish fervently that you Islanders had a much better supply of gonads.

> I wish you guys would get rid of your arsenal before you get too much into
> this macho 'real man' business.

Ah, and you'd rather succumb to the likes of Saddam etc or the late not so great Red Square inhabitants than to tolerate the "presense" of our defensive hardware? Truth to tell, we HAVE elimnated much of our arsenal. I know a bunch of former Minuteman sites that are now vacant lots. But hopefully we can survive the Clinton/Gore era with enough of it intact to keep YOU free, too.

Hang in there, Pal. I'd bet whoever is left overe here with any sense of responsibility will come to your rescue yet again when it becomes necessary. And your post makes it quite clear that it WILL again someday be necessary. Some folks just never learn......

There's an aftermarket RAM board made in Spain, I believe which uses no battery, has better features than the original, according to users, and costs much less, shipped. I don't have the details in front of me but they can be gotten from others on the Icom list and the Icom net.

That's interesting, Reg. If the end of your horizontal antenna
is pointing toward my vertical antenna, your horizontal antenna
is parallel to my vertical antenna. Parallel antennas are
usually best case, but in our case, it is worst case. :-)

Any one using amplifiers with High Sierra screwdriver antennas? If so, how many watts, what kind of amp and how do you have the antenna grounded (bonded) to the frame of the vehicle (more than one braid, solid copper strap, other)? Do you use any type of cap hat? If so, what kind? How big? Do you need to tweak the tuning from barefoot position when you engage the amplifier? Ever have any corona?

1228. Re: Trying to measure antenna Z through feedline

Newsgroup: rec.radio.amateur.antenna

Message-ID: <ERjK5.9789$mC.669979@monger.newsread.com>
Source record: 177577

Hello all,

Thanks to Richard C for referencing Reflections for this procedure. However, I'd like to clarify a point Richard made concerning 1/8 wl lines for the measurement.

There are two programs in Reflections, one for measuring and calibrating the feed line of any length for use at any frequency, including the effect of attenuation. The second program is for actually measuring the antenna feedpoint impedance through the line calibrated with the first program.

The reason for using 1/8 wl line for the feed line calibration only is that this length produces the most accurate data concerning the constants of the feed line, minimizing the errors as Richard explained.

Once the desired measurement line is calibrated at the frequency where it's 1/8 wl, it can then be used at any frequency, whatever its length, because the calibration procedure allows it to be used at any frequency, with the effect of attenuation included in the calibration measurement.

To confirm the accuracy of the measurements with this procedure I measured my 125-foot dipole with two different calibrated lines, one 1/4 wl at 3.797 MHz and the other 1/2 wl at 3.782 MHz. This difference in line length will yield the maximum error available for comparison.

The measurements were made with a General Radio GR-1606-A RF Impedance Bridge (years before I obtained more modern digital RF impedance measuring equipment), measuring line input resistance, reactance, and SWR, and then transforming the data through the calibrated line to the antenna terminals. Plots of resistance, reactance and SWR at the antenna terminals with each feed line resulted in almost perfect overlays, as can be seen in Fig 15-1 in Reflections. The overlapping plots also confirm the efficacy of the W2DU balun, because if common mode currents were flowing on the feed line the impedances appearing at the input of the feed line would not have transformed to nearly identical plots of antenna impedance using 1/4 wl and 1/2 wl feed lines.

Did not know 75 ohm CATV hardline had a "braid" as all the stuff I get for
free is solid center and solid skin, covered by a rubber coating, and it is
direct burial stuff. Have had 3 runs of 230+ feet in the ground for 2 years
now with no problems, and last fall I even had a lot of fill dirt brought in
via 5 ton dump truck that drove over the hardline that was only burried
about a foot below the driveway with no ill effects.

Hi Walt,

Thanks for the clarification. I would like to point out that my
technique employs a variable length transmission line (much like
Cecil's except mine is switch selectable binary progressions of coax).

Due to your compelling logic for the line calibration, I typically set
my variable length line so that it is always establishes an odd 8th
wave long, length during measurements (ie. in combination with all
line lengths between the source and the load).

I sent a PDF copy of Chapter 15 from Reflections to Jerry, using the email address: jbhall1282@my-deja.com, but it was returned 'user unknown'. Can anyone please help me in getting this PDF file to Jerry? And would anyone else like a copy of this data I described in the above post? Let me know and I'll send it.

Walt, W2DU

Alas Rudy, NOWHERE did I say or mention HARDLINE 75 coaxial cable; my
experience has been with RG59 and RG6 that have had flooded braids. Some
other posters have
confirmed that hardlines may also have the flooding compound to protect the
aluminum
sheath from corrosive conditions--that is news to me but I certainly dispute
their claims.

I have never seen "a rubber coating" used on any type of CATV
cable, so you are indeed one up on me..

Announcing the latest in frectal technology!!! The frectal probe. In a blur of shiny activity the latest in antenna design is nearly complete! After bribing a few law enforcement officers I was able to scale this massive structure last night and completely cover with tin foil. Actually, it may not have been needed as the monument is covered with scaffolding. But I like the smooth shiny look. So does the President. He sent one of his lackeys over to see what I was up to this morning. "No it wasn't Al Gore". The prez notified me that he had a few of those in his bathroom medicine cabinet. The matching device is not yet complete, but hopefully will be able to get on the air before the next 10m contest. An ez. file of this antenna can be had maybe next week. Then again, maybe not. To see this technological marvel click here:

No. I don't think so. I couldn't even attempt an analysis of the
situation, but my understanding is that most power amplifiers are
essentially VOLTAGE sources. Yes, you are supposed to get max power out
when the load is a conjugate match for the source, but the efficiency of
such a system could never exceed 50%. Regarding the impedance of the
electricity supply, I don't think that the electrical company would want
to lose 1kW for every kW you were using. Where a TX gives max O/P into
50 ohms, I suspect that this work of the SWR protection circuit rather
than proving that the TX output impedance is 50 ohms.

That's OK if you have a 'well-behaved' source impedance. However, I think that the Q of the PA tank circuit (even if this is 'disguised' as a multi-section lowpass filter instead of the good-old simple pi-tank) will change with the load impedance (highest Q when the load is low, and vice versa?).

Yes, with a generator having a constant source resistance you can determine the O/P impedance by the ratio of O/C volts to the S/C current (but don't try to measure a car battery this way!!). Another easy way is to load the generator until the O/C voltage is halved, then measure the resistance of the load. For the daring, you can simply use any load which gives a measurable voltage drop (say, by 5%) then do a simple calculation. But not, I think, with an RF PA stage.

There's at least 2 different sources for replacement boards without
batteries - both in the over $100 range. So - you go for the battery
in the $5 range (for 2 batteries). If you're careful, you just bought
another ten years of life for about 5 bucks, you have an extra 3V
coin cell on hand, and you save over 100 bucks.. If you aren't
careful, you buy the expensive board to correct your error.

The replacement board approach is great when the original
board loses its brains. And it provides extra memories, if
that feature is of interest. Anyone contemplating replacing the
battery should look into the replacement board before opening
the radio. go to the following url:
http://www.ameritech.net/users/willco788/index.html

The SWR protection circuit is there to prevent you from damaging the PA
from excess voltages when the load is high, and from excess currents
when it is low. Either side of 50 ohms, it cuts back the drive to the
PA, and thereby cuts back the power. If it's really doing its job well,
it WILL give the effect of obtaining max power out when the load is 50
ohm, but this has nothing to do with matching the load to the source.

Ian.

1248. Lifespan of Hardline Coax

I have several spools of old Alumafoam (Times Wire) that have been in storage for about 25 years, both 7/8" and 1/2" sizes. I have heard these products have a finite lifespan, and I was wondering what the failure modes for these cables normal are--increasing losses, etc.? And, I am was wondering what causes these cables to deteriorate with age. I am planning to use the cables next year on a new tower installation, and I am wondering if I should worry about the cable because of its age; or is it worth the bother of going through the motions to measure the losses using a signal generator and my Boonton microwattmeter? What experiences have others on the group had with aging hardline?

Source record: 177597

Did not know 75 ohm CATV hardline had a "braid" as all the stuff I get for free is solid center and solid skin, covered by a rubber coating, and it is direct burial stuff. Have had 3 runs of 230+ feet in the ground for 2 years now with no problems, and last fall I even had a lot of fill dirt brought in via 5 ton dump truck that drove over the hardline that was only burried about a foot below the driveway with no ill effects.

Braid is the wrong term it is a sheath that is aluminum and wraps around the aluminum jacket. And man is that sheath like a knife, it will cut your hands up so be careful!! If it is CATV hardline that is for burial it is "flooded" and has an armor coating as well. If it does not have the armor coating it ain't for burying but it can be buried if it has the plastic outside sheath. The armor is to protect the cable from being crushed by rocks etc.

This hardline can take a hell of amount of abuse.

Hope this helps.

Hi Pete,

On first pass, the principle mode of deterioration is the migration of jacket impurities into the center conductor insulator. This is usually performed through water as the vector of transport (rain or ground water when in the environment). The jacket and center insulator both being plastic based means that this migration takes some time to occur - unless it is in an extremely distressed environment.

This of course is a theoretical explanation. There may be other considerations (like the center conductor uses air insulation). It would be far simpler to connector up both ends, connect a good dummy load and measure the power into the cable and the power out of the cable (use the same power meter at both ends). Compare the dB loss to the published figures and you should have a pretty good picture of the condition regardless of service or age.

W9NTP has been running a KW on SSTV in his trucks, recently a Suburban, for a number of years, mostly on 20. using a Heathkit SB220. Contact him for details on
problems & solutions found.

A number of years ago I could shut down the electronic ignition on a Renault Fuego by keying my 25 watt 2M FM rig if the ground contact on the antenna was not making a good contact with the metal car body.

Ford used to hire people to keep track of what make of car had its ignition system killed by getting too close to the Voice of America antennas. They were also concerned that the ABS brakes could lock up or airbags might deploy!

Nissans put out a spurious signal on 146.985 Mhz which opens the squelch on a 2M FM receiver.

I have both the MFJ 259 & the AEA CIA-HF. I never use the MFJ any more except when tuning a 2M antenna. Wanna buy it? The AEA is especially helpful with the PC software feature. I disconnect my antennas from the rig and run a graphic plot which I print out & save. In case of trouble (or a solar flare total dropout), I rerun the graphic plot from the AEA and see if the antenna has a problem. It also shows me the SWR curve when the antenna is wet or Icy (beam moves down about 70 KHZ on 20M when icy or frosty.)

I am waiting for a new VHF/UHF version due out last June.

This was a rather ugly and pretentiously "low" peice of advice for a man with a problem Louis. I live in a fairly exclusive area on the Mississippi Gufl coast, with all the restrictions one could ask for and my 80/40 attic dipoles do a pretty good job for me on all bands (less 160). I'm a County Hunter Louis, I listen to weak signals all day and the mobiles are hearing me just as well as most of the stations with outdoor antennas, dipoles, verticals and beams. I put my 3 element 2mtr beam on TV rotor up in the attic and a 2 mtr/440 mobile vertical (mag mount taped to AC duct work, it's alluminum, to get as much of a counterpoise as I could. It works very well with my 2 mtr/440 HT.

I might note to all that I do not run an amplifier now, but will when I figure out how to keep the garage door from going up and down when I run my amp. Other than the door I don't interfere with anything that we are aware of, 'cept for that darned door. The feed point of the dipoles are just about in the center of the attic and I just stapled the wire in several places along the rafters, making what ever turns I needed to in order to have the configuration of the 80 with as balanced a set of bends on either side of the center feed point as I could. The 40 was a no sweat inverted "V" just stapled to the roof joists.

I may try my Screwdriver up there and feed my TS450 with it. Iv'e never used the screwdriver, it's still brand new. I only mobile ocassionally nowdays, so I have that rig by my bed to enjoy when resting or just feeling lousy or lazy :o) ....

My wife really wanted this house, so I solved the restriction problem to let her have the house that she has allways dreamed of us retiring to.

People have antenna problems and antenna restrictions placed on them all the time, but are not financially able to "buy some acreage" and put up an antenna farm. They are forced to do the best they can with what they have. Just like we did once upon a time. We need to be more thoughtfull of our buddies that do have problems but not the funds to do the best, just need something workable to enjoy as much of the hobby as they can..

Take care my friend, may God continue showering us all with his blessings,

Butch Magee KF5DE

I've had two runs of 9913 buried for over 10 years and I don't perceive
any change in their operational characheristics. Surely critical
measurment would show some changes. Nothing lasts forever, but if hard
line or even coax with a good quality cover is buried carefully -the
comment about rocks is certainly on target- it CAN last a long time.
There are no guarantees.

1259. Scanner antenna connection problem

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-28 01:56:46 UTC
From: MEL <melnadja@sisqtel.net>
Message-ID: <8tdbp101dik@enews3.newsguy.com>
Source record: 177612

I have a problem with an external antenna connection for my new desk top VHF/Air/UHF Scanner and am looking for the most appropriate News Group to post a message with the problem. Can anyone tell me what NG I should try? This NG is the closest I could come up with.

Here is the problem: I am running RG-8 coax cable antenna from the scanner to the antenna. Today I bought a PL-259 UHF - Solder Type Connector at Radio Shack to replace and existing connector. I put the new connector on the cable per the instructions that came with it but found that when I first put the connector center prod) in the center hole of antenna receptacle on the scanner, the scanner works OK. But as soon as I attempt to secure the scanner and the cable by threading the connector to the scanner the transmissions stop. They stop as soon as I touch the two metal parts together. If I pull the threaded coupling back and just leave the center prod sticking in the scanner, the transmissions start again.

If you can help I would appreciate it. If there a more appropriate NG to post this please advise. Thanks

1260. Re: HF attic antenna adivice, GOOD NEWS/BAD NEWS

Source record: 177609

I agree, for example I have a 10m 1/4 in my attic, compared to a A-99 (1/2 wave end feed) outside, the attic 1/4 wave is only down about 3/4 S unit down. (both antennas feed at about the same height, the "99" is about 8 ft taller at the top). As for interference to others people equipment chose your modes, power and bands wisely. Test all on you own phones ect. Also check out you covenant agreement carefully, If there is no provision against "radio transmission from inside dwelling" (most covenants only cover "outside antennas") or something similar the issue will be between you and your neighbors and you not your association.
Good Luck and Have Fun!

1261. Antenna Question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-28 02:22:05 UTC
From: Adam <radar_radio@yahoo.com>
Message-ID: <svkds86f2oolfa@corp.supernews.com>
Source record: 177610
Cross-posted to: alt.ham-radio.dxing,alt.ham-radio.hf,alt.ham-radio.ssb,rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.equipment,rec.radio.amateur.misc

Hello everyone. I'm fairly new to HF and have a few questions about my antenna setup.

1. I have a G5RV Dipole up about 40' set up as an inverted "v", and use it on 10-80 meters with an external tuner. I just got a new rig with a built-in autotuner. My question is: will the autotuner handle the SWR of the G5RV as well as my manual tuner does, or will I be better off to continue using the manual tuner? II have heard that autotuners have a low tolerance to high SWR, and in some spots, the SWR on the G5RV is very high (3.1+).

2. How far should the ladderline and coax be from the leg of my tower? Do the "arms" of the antenna have to be in a V shape, or can I string them to fit my lot (If I do a V config., one arm hangs about 10' above my telephone line, and I don't want to do that).

3. I notice that on 40 and especially 80 meters, I get RFI on our TV's and phones as well as radios, but only on occasion. Would installing a good low-pass filter help to resolve this situation, or should I look into installing line and high-pass filters on the effected equipment?

Any information would be greatly appreciated!

Thanks
Adam

Matt is correct. The stuff designed for direct burial is armored. The
corrugated armor is REALLY sharp. The sheath is not that bad. If you
can find it the flooded really is the way to go.It is a little messy to
splice but some solvent will remove the flooding compound. Odds are a
little talking to the guys at the local cable company will get you some
for free. There are always partial reels left over and frequently they
have to pay to get rid of it.Try to talk them into giving or trading
you some pin connectors and spice blocks also. Then you're going to
need a coring tool also. Actually maybe offering either a few beeers or
dollars would probably get one of the guys to splice it for you. There

is a fair chance one of them there is a ham. The .750 is really low loss. P3 .750 cable only loses 1.74 dB per 100 ft. @ 1 ghz. If you go for the .500 cable you're looking at 2.52 dB per 100 ft at 1 ghz. The non armored cable will work direct buried. It will be better protected in conduit though. I am somewhat lazy too, I don't like to have to dig a long trench but once.

Nope, I've been considering the Frectal Throne. A small loop that would be used from 20-10 m. Much like your AEA, MFJ small loops. The clincher in my design is it could easily double as a copper toilet seat. But due to rf concerns I don't think I'll advise QSO while SOP. MK

Matt is correct. The stuff designed for direct burial is armored. The corrugated armor is REALLY sharp. The sheath is not that bad. If you can find it the flooded really is the way to go.It is a little messy to splice but some solvent will remove the flooding compound. Odds are a little talking to the guys at the local cable company will get you some for free. There are always partial reels left over and frequently they have to pay to get rid of it.Try to talk them into giving or trading you some pin connectors and spice blocks also. Then you're going to need a coring tool also. Actually maybe offering either a few beeers or dollars would probably get one of the guys to splice it for you. There is a fair chance one of them there is a ham. The .750 is really low loss. P3 .750 cable only loses 1.74 dB per 100 ft. @ 1 ghz. If you go for the .500 cable you're looking at 2.52 dB per 100 ft at 1 ghz. The non armored cable will work direct buried. It will be better protected in conduit though. I am somewhat lazy too, I don't like to have to dig a long trench but once.
73,

If anyone needs 75 ohm hardline. I would advise people to speak to their local CATV company. We always had partial reels and if you talk to a technical supervisor you just might get all you need. It is best to go in person since if you call the gals on the phone might not have a clue what you want and give you the old brush off. As far as connectors and coring the cable Bill is correct a six pack or a few dollars goes a long way to getting that done, lol

Hey I was the only ham who worked at my company, which was a-ok by me, when we switched from microwave links to fiber optics guess who got all the transmitters and Andrews microwave dishes, lol

I use a W2DU bead balun to make the transition from RG-213 (about 13 ft) out of the tuner to 450-ohm ladder line. Works great on 80 - 10 with a 20-meter EDZ (88 ft long at 33 ft high). I also use an identical setup to the ladderline that feeds a 40-meter horizontal full-wave loop.

There is no compelling reason to prefer the 4:1 balun over a 1:1 since the impedances involved will never be either 450 ohms or 50 ohms on any band, other than by sheer accident. I believe that the current-balun configuration is much to be preferred over the voltage-balun format in this application, hence the W2DU baluns here.

All you are trying to accomplish is to ensure that a minimum of current flows on the outer braid of the coax. A choking action is what is needed, not any sort of impedance match. Thus, a current balun is called for.

With hard line having a solid outer conductor, I wouldn't think jacket impurities could contaminate the dielectric.

There are plenty of installations using Heliax foam line that are 40 years old and still working.

One other failure mode I can conceive of (but have no evidence that it actually happens) is deterioration of the foam dielectric. The material used is generally foamed polyethylene which is remarkably stable. If you have access to any kind of an impedance bridge, you might want to determine the characteristic impedance of the line using the open and short method. Probably not necessary, but if you've never done it, it can be a fun learning experience. (You can also determine the loss per wavelength and the electrical length of the line this way. Once you know the electrical length and the physical length, you can determine the velocity of propagation.)

Ten to twenty turns of coax on a 2L pop bottle works pretty well.
Some lengths of ladder-line are better than others. EZNEC, and other
programs, allow one to choose an optimum length of ladder-line.

There was a thread on this subject some time ago. As I remember the
experts advised that rather than use a 4:1 voltage balun one should just
use coax that would withstand the voltages involved, just long enough to
get outside to where you can easily transition to open wire or ladder
line, and connect the coax directly to it, decoupling by using a proper
current (choke) balun just before the transition.
This eliminates the problem of a voltage balun seeing widely varying
impedances which it almost certainly can't handle and provides a
balanced input to the ladder line. The short run of coax will offer
little reflection loss, and if it is properly rated will handle the high
voltages that will sometimes be involved without any problem.
The SWR on the coax can become quite high with the inevitable mismatch
sure to occur with wide frequency changes as the antenna moves out of
resonance, but as long as the coax -and the tuner- is rated for the high
voltages involved it will cause no problem. (You didn't say what power
level you will run. Coax and tuner ratings for high power usage must be
scaled upward for the much higher voltages involved.)

The PL259 you just installed is almost certainly shorted. It takes very little to short it-one single fine strand of wire from the braid touching the center pin/conductor will do it. The radio plays when you touch just the center pin to its contact but when you screw on the barrell of the PL259 the short inside it kills all the signal. I've seen it many times.
There is an art to installing PL259's and it takes some practice to get them right. I'd bet that is your problem.

Attic antennas are a crap shoot when it comes to interference. It may
depend somewhat on how the house is wired. Some houses route all the AC
wiring through the attic then down inside each wall to the individual
receptacle outlets. There is almost always overhead wiring for ceiling
lights and their switch legs. Other houses use the basement and come up
to outlets, thus less wiring close to the antenna in the attic and less
likely to induce RFI onto the AC system. Higher pitched roofs can mean
more distance from the antenna to housewiring. The idea is to keep as
much distance as possible.
One attic installation I helped with involved paralleled dipoles on
40, 20 and 10 meters fed with RG58, tacked to the roof rafters with the
40 meter wire Z'ed as necessary to fit the space available. The antennas
worked FB, and even loaded and worked FB on 75 meters through a tuner.
Making contacts was no problem. RFI problems were to a hardwired smoke
alarm high on the kitchen wall and to the cordless telephone. They were
not present on all bands indicating they might be the result of a
resonance in the AC wiring, but they were not cured.
Looks to me like one has to just evaluate what you have, and make the
best attic installation possible, then live with whatever RFI that you
wind up not being able to cure. Chances are better than even there will
be some. And you'll *always* have the TV horizontal frequency "birdies"
every 15.75 kc to keep you company on receive, at least until HDTV

replaces the present analog system. Who knows what we'll have then? I'd bet the digital sets will be worse.

hi i am Taka JR3TVH from JA.
it actually fit until 1 to 600ohm around. generally in JA, ICOM AH4
though it works above 80m, it is stable and very popural in Japan now.
it is small,light.
i have SGC230 but it also limited 150watts PEParound as same as AH4,Alincos.
i recomend for OMs , JRC one. comparing from other AH2.AH3.SGC230,and
its 500watts type,
This automatictuner has more dia. coils for each band for high power
and especially for 160m use.but if you put and watch your power below
150watts around, it will not saturated or burn
if you put a carrier signal for long time. sat@arrl.com

> Announcing the latest in frectal technology!!! The frectal probe. In a
> blur of shiny activity the latest in antenna design is nearly complete!

>

Was able to do some testing this evening with the Frectal probeï¿½.
Comparing the tin foil covered version against the scaffold version,
could tell very little difference. If anything the smooth version gave
the best performance on 160m tonight. We will continue to run more tests
on this breakthough technology this weekend.
The scaffold version loaded well in tests we ran before the tin foil
covering last night. But as in recent modeling tests, after comparing
the two versions I could tell little advantage to all the meandering
wires which the scaffolding added to the structure. We had quite a group
of people interested in this new antenna and many hung around the
monument to watch me get the runs on 160m after we got it all tuned up.
The performance on 160 and 80 m was awesome. I was able to talk on 1.890
kc and hear my echo every time I unkeyed as the signal blasted it's way
around the world and back to my receiver. I'll post a pix of the
scaffold version of this antenna for reference. It did play well, but no
better than the solid mass of foil. In the picture you can see the van
we were operating from. The antenna was base fed with 213 coax. As we
are a small fledgling company I couldn't splurge on hardline. Overall,
I'd have to say it's been a thrill to test this theory in such an
historic setting. I had never been to DC before. It ranks up there with
my operating a special events station on the Battleship Texas. And the
prez seemed to be fairly nice too. I never actually got to see him, but
his relayed comments about his own version of this antenna were greatly
appreciated. "I guess his a UHF version".

Hope this helps...

hi for all , i am Taka JR3TVH from Osaka.
i am donated SD antenna, DK3 of Don Johnsns. it is so unique and happy
to me.
but installtion to new vehicle of mine, SUV montero, i need one like
High sierra HS202.
i cannot drill any hole to new SUV,you know.
and HS1500 price up and HS1500MarkII i saw on the HS website.
i want it ,the later 1500 is okay but he changed his website and more
expensive one,called MKII.
so i can not handle my wallet now.hi .Other progresssed DK3 type
antenna and StealthII.III.i find
them on the internet. What is the difference of them.
if anyone donate /sell low priceone , i would compare them all. i am
very interested it.
in JA there is few SD antenna. and ATAS100 coil is not big dia.73
mail me anyone!

Well, since the topic of this thread is "HARDLINE" maybe Rudy made a logical
assumption that you were talking about hardline.

And because something "is news to you" you automatically "dispute it?"
>
> I have never seen "a rubber coating" used on any type of CATV

Apparently several of us are one up on you. I have seen CATV "hardline" that has a jacket, that while precisely speaking isn't "rubber" is certainly a "rubber-like" material, that is designed to protect the aluminum shield from the elements.

I am interested in buying an inexpensive 1750 meter transmitter and or beacon.Homebrew is ok and may be tube or solid state.
I am disabled with a neuro-muscular disease so it can not be a kit because I am unable to solder small components any longer.Price is also a concern due to fixed income so if you have anything you think I might be able to use please e-mail me with details and price.

1276. Tuner to open-wire line

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-28 06:09:54 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <39fa3653_1@news1.prserv.net>
Source record: 177608

I would like to connect a tuner (with only coax output) to 450ohm open wire which goes to a 45' dipole that I would like to try to use on several bands. I thought I would use something like a 4:1 voltage balun --- not a close match, but probably good enough. However, in reading about voltage baluns the handbook (and several other books) imply that they are reasonable solutions only when each side is matched to its load. The dipole will probably present a wide range of real/complex loads on various bands.

What is a reasonable way to connect the tuner to the line in this circumstance?

Bill Ogden

One night/early morning on my old radio show I played that RIGHT after a
recording of Neil Armstrong on the Moon. Ah, free-form college radio, makes
14.313 sound like a Sunday School lesson.

Your luggage is in the mail.

Trust me.

Consider the approach used in the ARRL-designed tuner in Chapter 22 of the 2000 ARRL Handbook.

If you are really concerned about this, wind the balun as a 9 to 1
instead of the more common 4 to 1 ratio.

Might be an ugly piece of advise but it was realistic. Your in a house the guy asking the question is in a townhouse. His neighbors are going to scream bloody murder when he keys up on anything more than 25 watts. If he is happy running 25 watts or there about then he should do fine. The guy should be prepared for the worst and that is what Louis was doing.

> post this please advise. Thanks

Sounds as though there is a short in the coax. If the only thing you changed was the connector- then you have a short in the connector. An ohm meter test will proves this out- you may want to disconnect the antenna as it may be designed with a DC short itself, which would mask the coax short.

The auto tuner in my Icom 746 handles the G5RV just fine on all bands including 30 meters where it isn't "supposed" to work. Your results may vary.

According to the folks at Radio Works, a G5RV is not very good in an inverted V configuration when the angle of the legs is less than 140 degrees. Too much radiation straight up. Check out www.radioworks.com Of course, if that is all you can do, it is better than nothing. My G5RV is an inverted V and it works OK but is being replaced this weekend with a ladder line fed dipole.

If you haven't yet bought the G5RV you might consider a shorter antenna that you can flatten out - such as the Spi-Ro AS-2. It is only 70 feet long works 160-10, uses ladder line and requires a tuner. See www.spiromfg.com

W9INN makes a space saver dipole covering 160-10 in only 71 feet. 80-10 in 42 feet. Look for the tiny print ads in QST. They are rather expensive compared to the G5RV or the Spi-ro product and aren't advertised to cover the WARC bands but I don't know why they wouldn't as they are ladder line fed through a tuner.

For your, RFI make sure you run the matching section of the G5RV straight down and keep the coax away from the antenna. High pass filters may help, also torroids on the phonelines and AC filters on the TV. Radio shack sells all that stuff. I originally had a lot of trouble with RFI with another antenna but it was solved by relocating the feedline. I wasted a lot of money at Radio Shack buying filters to no avail.

Let us know how it turns out.

Hi Paul--

You'll probably have to space your pc board above an aluminum groundplane of some kind--perhaps at least a few inches above the surface. This should give you some consistent isolation from whatever external surface you mount it on--and allow you to optimize it on the bench. Probably hit Walmart and get a nifty plastic "mirowave-proof" food container to put it in?

If looks mean anything that stuff would perform quite well buried. It
appears that it would probablly last as long as you'd want it to.

Rhatt wrote:
"I would like to try a Rhonbic array for working 10 meters."

The U.S. Army supplied rhombics for use with radio sets AN/TRC-1, -3. and -4. in WW-2. Using the 70-MHz version having 4 wave lengths per side, this would scale to 29 MHz as follows:
Leg length: 115 ft. (2 ea. 230 ft. wires)
Height: Use 4 ea. 60 ft. poles for support.
End poles: 290 ft apart
Side poles: 125 ft. apart
A 600 to 800 ohm resistor is used to terminate the target end of the rhombic.
A balun and match is used between the 600-800 ohm rhombic and 50 ohm coax used with the radio set.

Gain would be about 11 dbd in free space, but depends on ground conductivity under and around the rhombic and could be more or less than 11dbd. Gain is the same if the termination resistance is omitted, but the rhombic will be bidirectional. The resistor makes it unidirectional.

The advantage of a rhombic is is ability to operate over a wide frequency range while maintaining a relatively constant impedance.

For single-band operation, doesn`t a Yagi look very good as it needs only a single support, can be rotated, and takes up much less real estate?

Best regards, Richard Harrison, KB5WZI

While my first inclination was to say if your looking for sympathy, you can find it in the dictionary between shit and syphilis....

Upon reflection, I hope to give you a serious answer. No one on this group could get Nathan fired except Nathan. Universities are the most politically correct institutions in society. As such, the firing of anyone is done ONLY after exhausting all other avenues and the utmost concern for the rights of the person being terminated. While missives from this group could start the process in motion, they could hardly be responsible for the conclusions. Having been on the receiving end of his vindictive nature, I can only assume that the supercilious, vitriolic personality carried over to his job. The mental instability shown on this newsgroup had to manifest itself in the classroom. Dr. Cohen is solely responsible for the events that have befell him. He is to be pitied, as his friend you have the obligation to encourage him to get some professional help so he may get his life back on track. Perpetuating the myth that his problems are the fault of others dos him a disservice. I expect however, much to the detriment of his mental health, you will continue as a cheer leader on the "sue the bastards" team. Mores the pity!

The ARRL antenna book has been publishing rhombic designs for decades. You can probably find a copy at your local library. There are many antenna designs on the web. Try a search on "rhombic antennas" or go to:

http://www.ac6v.com/pageant.html

Good luck...

Found it! Pasting the contents of my file:
EPROM/RAMBOARD
by Roberto Nardo, IK2RND

For ICOM IC-751/A IC-751 IC-745
ICR71E/A and IC-271 IC-471 IC-1271

The EPROM/RAMBOARD card directly replaces the ICOM RAM
UNIT EX-314 and EX-314 # 01. No soldering is needed and the
frequency coverage is extended from 10 KHz to 30.9 MHz (for HF Rigs)
and for the IC-271 2 meter radio, the range is extended to
142.400-153.990 MHz.

<snip>

Hi Wayne--

>...it's always someone else's fault.<

Phil never specified if this disconnect involved FAS, BU Metro, or Amway, so how do we even know what he's talking about?

Regardless, I agree with you. Those unwilling to assume responsibility for their own actions often seek revenge by lashing out at others. But, don't worry about getting a "subpoena". A "subpoena" is simply a court order compelling a third party to produce take-out consisting of a particular type of elongated sandwich. The legal term that compells someone to appear and testify at trial is spelled a bit differently.

My 97 chev 2500 van would amuse on lookers when I transmitted on 80, 40 or 20. Anything over 25 watts on 80 meters the windshield wipers would start. On 40 meters the interior lights and dash warning lights would turn on. 20 meters a warning buzzer would sound from under the dash. Transmitting at 100 watts would kill the engine.
Several emails to GM showed that they are completely useless (I already knew that after having transmission problems that they would not address).
Anyway, paying closer attention to grounding, PL connections and chokes have solved the problems, but have not tried more than 100 watts.

Yes, I agree with what Walt here says...I have a G5RV and use it with an FT-990 which has an autotuner and it works fine, my ant has several spots with swr over 3:1 and the tuner handles it fine...just for your info...

Rick- I think we can assume he meant BU. That is the only position we know of where other people control his employment. I note that some people are responding to the "hatred" post as if it originated with the real Phil. That may be true, in this case, but dont bet much money on it- history would lead me to think otherwise.

I'm sure we will hear more about this, and get LOTS of blame heaped on the members of the NG, because, obviously, it CANT be Chips fault- he is always blameless, and as pure as the driven snow.

I wonder if Cohendog got kicked, this morning?

Well, he wrote....

Congratulations you turkeys. You've taken someone whose done something
positive and through jeaolusy and hatred changed his life. You are to be
pitied.

Nathan Cohen has his position terminated on 1 Nov.

Now there must be assumed massive legal problems for those who have
defamed and injured this person. I don't think you have any idea what
kind of villany you have done. But I bet you will find out.

Phil
de N1ZKT

unquote...

But it's all horsehocky. The only person guilty of all this is Chip. If
he is indeed fired, it's his own fault. I'm sure the school did their
research before coming to a conclusion. They are not going to fire
someone just because someone off a Usenet group says it needs to be. I'm
sure they looked into it and came to their conclusion on the FACTS of
the case. Heck, I subtly tried to warn him months ago about braying like
a jackass on the internet, but nooooooooooooo, he wouldn't listen. I bet
he listens now. And I myself didn't have a thing to do with any of this.
I could care less, except that he clogs the NG up with clap trap. I sure
haven't been in any contact with his school in any way. I doubt I would
even want to waste my time talking to them. If he thinks the school is
wrong, he needs to hire a lawyer and take em to court. Trying to sue
anyone on this NG will be an effort in futility. But as previously

mentioned, he won't listen. He thinks he's Perry Masons lost step child.
But I don't think his ph.d covered law. MK

You could be having cases where it could run awful hot though. And you
can't really tell if it is or not.
That would make me very nervous. The built in tuners pretty
lightweight. And if it went south it would cost half a mint to fix.
But... it's your radio..:/

Hummm, I would think the height above ground would have more of an
effect on the radiation. Even a flat top dipole will shoot straight up
if low to the ground in WL. In a case like that the angle of the legs
has little difference. And even an inv Vee with a 90 angle will show
good low angle radiation if over 1/2 Wl high. MK

Sounds like one of two things may have caused this.

1) Grant money ran out.

2) He was found to spending too much time on the internet at work!

Either way, they wouldn't have fired NC for what ANYONE on the
newsgroups said unless it turned-out to be true!

Pretty sneaky huh. But don't worry, I'll quit. I just wanted to give him a taste of his own medicine. My antenna a joke of course, but if you didn't know any better you could mix mine with one of their creations and you wouldn't think anything amiss. It would fit right in. But since he seems to have been terminated from his school gig, I better slack off. I don't want to trigger any irrational behaviour. He might kick Cohendog again. I wouldn't want that to happen. MK

Rudy,
I run a high Sierra Screwdriver. I ran a Ameritron ALS 500M for two (2) years. If you read the specs from High Sierra , you will note 500 watts is about maximum. Most (I said most) screwdrivers apparently do not take anymore power, due to the material the form is made from, on which the coil is wrapped.
No tweaking, just drop the SWR flat and key the amp.
Ground, ground ground. Braid, strap etc.
Haven't run a cap hat. They sell one.
Hope this helps.

1320. Broadcast TV receiver sensitivity

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-28 23:32:28 UTC
From: Aaron Hanson <ha2@uswest.net>
Message-ID: <RIJK5.6166$YI5.319399@news.uswest.net>
Source record: 177568

Hi All-

I'm considering purchasing an antenna for the specific purpose of TV reception of CBUT (Vancouver Canada channel 2) from Seattle. I've determined the transmitter location and power, and with some basic path loss calculations I've decided that for the antenna and feed-line I'm considering, I'll end up with about -25dBm (3 microwatts) signal strength at the TV.

Now I realize I have no idea what range of signal strength is necessary for decent TV reception. Of course the TV specs say nothing about receiver sensitivity.

Does anyone know what range of signal strengths equate to decent TV reception in today's typical TV?

Thanks!

-Aaron

I use several long lengths of hardline for my 160M to 10M antennas. The cable was old when I got it and that was 15 years ago. The main problem has been kinking the aluminum when trying to unroll the stuff.

I run a multiple of a 1/2 wavelength to each antenna. This way the impedence is the same at each end, regardless of the impedence of the hardline. The trick is to find the magic 1/2 wavelength point. It is rather simple using the MFJ or AEA analyzers, and the hardlines are all about 200-300 feet in length, and the price was right (free)!

1323. Design, Calibration, Operation of SWR Meters & Reflectometers

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-29 00:03:50 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <8tfr7l$4t4$1@uranium.btinternet.com>
Source record: 177472

NOW AVAILABLE, Program "SWRMETER.exe"

This program models and assists with the design of the
common HF Standing Wave Meter. Enter its essential
characteristics and the program constructs it and calibrates
it against the users standards ready for use.

Input data includes source/Tx internal resistance if known.

Extensive notes:- Principles, circuit diagram and
description, key component values, points to look out for.

Enter any load impedance R + jX and meter readings of
forward power, reflected power, reflection coefficient
magnitude and SWR are computed. Indicated values are
compared with true calculated values.

Continuously vary all input data in small increments on a
what-if? basis while observing meter indications.

Operating circumstances, including input resistance of
source, under which measuring errors will occur are
demonstrated and discussed.

This program is contained in a single executable file of
64.5 Kilobytes.

NG:

I've been really busy for a while and haven't checked in to the NG lately.

And when I do... wham!! Wow!

I see that NC is now going to SUE Roy... What???

I thought NC loved Roy, at least he always seemed to defer to Roy more than anyone else on the NG.

What could Roy, the most professional person on the NG in my opionion, have done to offend Dr. Cohen?

I guess that's what happens when you don't tune in to the soap opera every day, you simply lose touch!

Apparently I missed a big part of the "Sue the World as it Turns" plot.

Regards to all, and "hang in there Roy",

-Peter K1PO

1325. A new satellite antenna design

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-29 00:29:18 UTC
From: "Dr. Robert Suding" <robert@qadas.com>
Message-ID: <39FB6F5E.F2F793B2@qadas.com>
Source record: 177471

I have been modeling an antenna for the forthcoming phase 3D satellite that should be of use to many amateur satellite entusiasts.

I am looking for a design that will have a narrow, high gain beam pattern in azimuth along with a arc pattern from 0 to 90 degrees in elevation. The front to back & side should be great to minimize terestrial QRM & QRN. The reason why I want this is so that I can track a satellite with a single standard rotator, such as mounting the satellite antennas above an existing HF triband beam.

A single yagi has a rather narrow pattern both in azimuth and elevation. So I tried modeling a pair of yagis, fed in phase, set at various elevation angles from 0 to 90 degrees.

I found a very nice 0 to 90 degree "lemon slice" pattern results when a pair of in phase 10 element VHF or UHF yagis are mounted with the lower yagi pointed upward at 20 degrees and the upper one is pointed upward at 70 degrees. The "software gain" on this antenna looked like around 10-13 db, about 25 degrees beamwidth in azimuth and 90 degrees in elevation. If true, this might be an ideal antenna for P3D.

Larger yagis had more gain at some elevations, but tended to have deeper null points. Shorter yagis had less gain, but the nulls were minimal. 10 elements looks like the magic number to me. For more gain, 2 X 2 arrays could be used if needed.

My initial modeling was with a conventional K1FO-like horizontal yagi, but I also tried crossed yagis in an X, not a T configuration, so that I could use circular polarization with phase reversal as I do with my present AZ-EL mounted satellite antennas.

The end result is a pair of 40 element antennas for the uplink & the downlink. The physical mounting could become interesting. The boom lengths for 2M are about 13 feet long and about 4 feet for 70 CM.

How about some help from you antenna modelers out there? Let's make this a really ham antenna project instead of all the stupid sniping on this newsgroup.

>Sorry Wesley, never seen rubber used on any modern cables as a jacket. If
>it is, it
>is rarity.

I do respond to my given name, so if you are trying to use it in a pejorative sense, you're out of luck.

From Webster's New Collegiate Dictionary:

rub-ber ... (snip) 2 a : an elastic substance that is obtained by coagulating the milky juice of any of the various plants (as of the genera Heavea and Ficus), is essentially a polymer of isoprene, and is prepared as sheets then dried b : any of the various synthetic rubberlike substances c : natural or synthetic rubber modified by chemical treatment to increase its useful properties (as toughness and resistance to wear) and used esp. in tires, electrical insulation and waterproof materials 3 : something made of or resembling rubber....

Note that I said, "precisely speaking isn't "rubber" is certainly a "rubber-like" material" So if I or anyone else uses the term "rubber" or "rubber(-)like" to describe the outer jacket material of a coaxial cable, I suggest that Webster would agree.

Elastic, tough, resistant to wear, waterproof, good electrical insulator, resembles rubber.

If it looks like a duck, quacks like a duck, walks like a duck.... It must be a rubberducky. (Sorry Pete, sometimes I just can't help myself)

1329. Butternut HF6V on 6 meters

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-29 02:37:25 UTC

Source record: 177476

Has anyone out there successfully added the 6 meter kit to their Butternut HF6V vertical? I cannot get mine to resonate anywhere I put it. According to Bencher, the top bracket with the wire attached goes about 3/4 wave length above the ground (~162") and the other about 1/4 wave length below that (~54"). The instructions state 151" and 58" I believe. However, nothing close to this seems to work. The SWR is 5:1 + regardless. If anyone is successfully using the 6 meter on their Butternut I greatly like to know how it is set up.

Thanks

Larry

-25 dBm will be viewable, but not noise free. I try to keep my signals above -10 dBm if I can. Modern TV sensitivity doesn't vary much. Figure a bandwidth of 6 MHz and a noise figure of 10-15 dB. Start from KTB = -174 dBm for 1 Hz.

Might be kinda fun to hammer two
copper pipes, one each into adjacent trees,
then run some ladder line up to your rig and
see what kinda SWR you get. The ultimate
stealth verticle. Hi.Hi.

Better yet, if you could get a copper
paint that actually had copper in it you could
spray paint selected branches to form a sort
of a fixed monster size Yagi.

1335. 40m slinky dipole, 1.12 SWR! But it wants me dead!

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-29 08:29:16 UTC
From: Jake Schneider <j4k3@texas.net>
Message-ID: <wdRK5.40133$d57.3871094@news4.aus1.giganews.com>
Source record: 177483

Hello all, this is my first post to the group, and I have a question. I have built a DSW-40 and tuned it properly I think, it worked the first time I applied power to it. Got the sidetone right on the carrier, zero beat a station with a TS-440, then listened on the DSW-40 and it was all good. I was enthusiastic to find a wealth of information on limited space antennas. See I am one of the damned, an apartment dweller. (First floor, PVC pipe damned I might add) So naturally when I saw information on the Slinky dipole, I rushed straight to Wal-Mart to purchase some slinkys and get it on. I was astonished to see that the swr was 1:1.5 even before I began adjusting the lengths! Yes it is against a wall, but still 1:1.2-1:1.5 from 7025-7130!! I unplugged the TS-440, and hooked the DSW up. I began listening to 7040, and sweeping around. Apparently all the loud stations were 5s, hrm. Previously, I used a random length of wire strung along the corners of my ceiling. I had the feeling that I was working the ground plane, and that is what prompted me to switch to the dipole. Unfortunately I've only made 4 total contacts the past two nights. All of them from Dallas,Houston, the farthest GA. (My QTH is Houston BTW) I have no real grounding scheme to speak of, god for bid someone find any copper in this complex. I guess the question is, what can I expect from such a slipshod setup? What can I do to improve it? Besides winning the lottery and moving to a mountain? Is 2 watts out in an apartment with lame ground even a reality? Am I expecting way too much? Help!$$!@

Station:

DSW-40 (I love this radio)
13.5v 7.5AH Lead acid gel cell (I use a APC UPS, to recharge it. I figure the circuitry in there knows how to keep it charged)
Slinky Dipole 7'6" each side fed with 52ohm coax about 8' up, inside the apartment!

Thank you,

Jake Schneider KC5UIV

I presume that the bicycle wheel is made of metal and that you have
wound the 100 turns around the (tyreless) rim? Surely this presents a
complete short circuited turn, and pretty well kills the inductance and
Q of your coil? Or is the wheel one of the 'avant garde' variety, made
out of plastic?

I believe that experiments HAVE been done to try and use trees as
radiators (such as tapping into a trunk about 1/3 of the way up and
gamma-matching it like you would a vertical mast). Probably best when
'the sap is rising', so efficiency would be seasonal!

Ian.

Coming from the cable TV world, I see it like this...

Most modern TV tuners have a noise figure of <5dB.

Using a NF of 5dB, a TV signal of 0dBmV (1mV) will give you a carrier-
to-noise ratio of 59dB (ie the rms noise in the NTSC 4MHz TV channel
video bandwidth) MINUS your 5dB, ie 54dB.

-10dBmV (300uV) should give you a S/N of 44dB (where you will JUST start
to see the picture noise beginning to increase because of lack of
signal). And pro rata....

If you are not too discerning, you will probably find S/N of ~34dB
acceptable (at -20dBmV, 100uV).

Now, convert your dBm into dBmV. 0dBmV is ~-58dBm. You have calculated
that you will get -25dBm - that's a staggering +33dBmV!! You could boil
a kettle on that! If you are correct, you will probably have to fit an
attenuator at the TV input! I wonder if your calculation is correct? Or
have I screwed up somewhere (it won't be the first time!)?

Ian.

P.S. I note that there is another posting from 'Crazy George'. I feel that his name reflects the accuracy of his information (no offence, CG!). Are 'dBm' and 'dBmV' getting mixed up? There's a difference of ~58dB.

You are well adrift in your figures, George.

American System M NTSC video bandwidth is only ~4MHz, and TV tuner noise figures are pretty low (<5 dB, I think).

Also, -25dBm translates into ~33dBmV - enough to 'boil a kettle on' in the world of TV reception! Getting dBm and dBmV confused?

Ian.

Hi Jake--

Unfortunately the antenna is a poor one for that frequency. If you are getting such a good, broadband SWR without doing anything to the slinky, then something else is resonating; probably your grounding systems and coax.

A very short antenna on 40M at a low height will be inefficient and radiate mostly straight up. This won't be useful for DX, if that's what you want.

remember: SWR only indocates a matching quantity and tells you nothing about how much RF comes out the antenna or which direction it goes.

I don't know f your radio, but if you have to option to choose other bands, especially 10M, I suspect that your limitations won't be as constraining, because the antenna will be a greater function of a wave higher, and not as electrically small.

I would think most hams running 2 watts are not expecting to hear the other station report 599 very often. My impression is that they enjoy the challenge more than the result. Hence the bragging rights associated with miles per watt. With an antenna inside an apartment, figure the erp is low anyway. With a starting point of 2 watts, you're at a disadvantage from the start.

Understand that many hams without 260 feet of space load an 80 meter dipole at the ends to make the antenna "appear" longer than it is. The slinky takes this approach to the ultimate by simply having one big inductor on each leg of the dipole. The end loaded dipole at least has some wire that radiates. The slinky has none. I suspect most of your power is expended in heating that big coil. You've proven you can make a few QSO's. Houston to Georgia under your conditions is nothing to sneeze at. Just remember effectively you're running QRPp, not QRP.

My sugguestions:

1. Apply the same sound antenna principles inside your apartment as someone who has acres of space for antennass. That is, get as much real wire as possible up as high as possible. Since your elevation limit is 8 feet, don't string wire around the room, string it around the whole apartment. Feed it as you would a random wire.

2. Many apartment dwellers stretch the longest dipole their place will accomodate (usually 10, 15, or 20 meters) the length of the apartment and feed it with coax. Restrict yourself to that band. Many years ago I put a 20 meter dipole inside my apartment in NYC. First QSO was USVI.

3. You gotta have a ground. Either a heavy wire out the closest window to a stealthy ground rod (since you're on the first floor) or at least a lot of copper wire around the base boards as a ground plane.

4. Take down those slinkys and give them to the kids. That's their intended purpose. Many on this group will tell you (correctly) that you can get a short piece of coat hanger to exibhit low SWR. It will still act like my first girlfriend - won't put out...

1342. Re: Fractal Geometry Insignificant ...

Newsgroup: rec.radio.amateur.antenna
Date: 2000-10-29 11:32:49 UTC
From: John Peterson <jpeterson@optushome.com.au>
Message-ID: <39fc0b83@turakina.six.asn.au>
Source record: 177490

I am only going from what the manual says and my previous use with and development of other types of models.

Here is my thinking.

1. The EZNEC program splits the antenna up into stright line "segments" and in the professional and registered versions this can be done automagically.

2. You do not get to see the segments it chooses.

3. Antenna wires in the model can only be straight lines.

4. A fractal to me is a shape of the same form within a shape (often repeated).

5. Now I imagined a real "arbitary" shaped antenna. I think for example of an antenna where two straight wires come together at an acute angle with a smoothed curve [I will use a 90deg pair of wires for example, joined by an arc of r radius].

6. ELNEC may model this as two sides of a box coming together with little straight bits (i.e. "steps") making up the arc.

7. These steps are in fact smaller versions of the larger shape, and inside that shape - thus fullfilling my criteria for a simple fractal design.

You may of course want to dissagree with this.

8. With a more complex "arbitary" shape where there is lots of wire in a small space in arbitary form this effect is magnified (rather than reduced) because ELNEC / you will chose straight lines it can handle.

This is why I suggest to be careful.

I would say about 90% of Mr. Best's minformation stems from the fact that he does not understand what a fractal is. As we now have a generation of very good texts and reference, widely available, on fractals, that is his concern.

In fact, every single shape that Mr Best presents in his 'random' lists--non BTW are "random"-- is either dominated by fractal shapes or (related and hard to model accurately)) meanders.

Thus, in a scientific forum, such as a peer reviewed publication, Mr. Best would be objectively disocuraged in presenting what amounts to false interpretation--that is, that the fractal shapes have no beneift. In fact, he seems to strongly support the opposite!

I, for one, hope Mr. Best actually writes up a paper, if for no other reason then he has demonstrated that the Cohen Hohlfeld paper of 1996 is correct:

1) the Small Loop Approximation (see, for example Karus's ANTENNAS) , which ascribes the rad resistance to the enclosed area of the loop, is INCORRECT; in fact, the area of the loop has nothing to do with the radiation resistance. Mr. Best has discovered for himself that the SLA will not only predict the rad resistance incorrectly, but similar values of rad resistance are obtained with radically different values of enclosed area;

2) A fractal loop has a much higher radiation resistance, in this case attribuatble to the two current maxima.

What Mr. Best is not yet seeing as the scientific kernel is the limiting radiation resistance of a resonant loop in such a small form factor. That fact that he has a sample of designs which all are over 30 ohms says a lot (or should to him). Now: what is the best way to approach--or acheive-- the asymptotic value of rad resistance? My ongoing work on this question suggests that the limit is approximately 36-38 ohms. However, I do have some fractal loops--including MI2's, which present extremely good SWR's (of order 1.2:1), suggesting that the NEC modeling has some inaccuracy in getting precise values.

As I have stated, this info will be published after submission in January.

Cordially,

NC

Neither, as the article here on the web shows, you remove all the spokes, (I had my choice of free rims from a bicycle repair shop that was happy to have one less to throw away). Saw the rim through at one point, and screw the two ends (Separated by abput an inch) to a small block of wood. This removes the short and provides for me at least, a mounting for the loop amplifier and the short loop of wire for the "hanger". There is also a "wrap" of thin packaging plastic between the rim and the winding, just to cut the capacity to the rim, and when completed, the plastic is wrapped over the winding as well. Aluminum (Aluminium?) foil is wrapped around the complete assembly (minus the 1 inch gap), crunched to a conformal shield and grounded to the rim.

Use Google or some such to search for WWVB or VLF and you'll come across the pretty ingenious approach.

There's a hundred ways to make the loop, almost any of which results in a much larger capture area for the signal than a ferrite loopstick, and still providing much needed directivity to kill the noise in other directions.

Adam, As you well know, opinions on antennas are a dime a dozen, everybody has his favorite. I tell you from first hand experience (been there, done that, got the T-shirt to prove it) throw that G5RV away and just put you up an inverted V or a flattop for 80 mtrs feed it with coax (rg8x is light and will handle up to 600 watts and is inexpensive) Your'e autotuner will love the Vor strait dipole, and I will bet you will hear better and receive better signal reports.

Hi Bill--

No;

I do not publish in ham magazines anymore. I have two scholarly journals in mind. Probably take a while after acceptance, as journals tend to run slow.

After that I can see placing a summary on the ham page, on its new web site.

Cordially,

NC

1350. Re: Tuner to open-wire line

The RadioWorks has a 4:1 current balun that is great for you're application. I use the same configuration and love the thing .

I'd say you're doing great for 2 watts, indoor antenna.

Why not put a screwdriver antenna on your car? Drive it to a high spot
(well, okay, Houston has no high spots -- maybe out to Memorial Park
or whatever) and work dx from your car :-)

With 2 watts and a low antenna system your results are probably good.
The dipole does not need a ground to work with, but the ground does
provide a place for undesired harmonics and things like that to go.
While not really recommended you might try using the ground of the AC
outlet for a ground. Just cut off the flat prongs of a power cord and
use the round one.

You might look for the frequencies of the QRP nets. They are the ones
using low power and are looking for the weak signals.

Hi Bill,
I'd go with a W2DU choke balun made from ferrite sleeves. The choke balun reduces currents on the outside of the coax shield. It doesn't guarantee that the currents on the ladder line are equal, so there may be some feed line radiation. But that shouldn't be a concern.

I have a similar setup at my place and have never had a problem with shocks. The ladder line feeds a 200' dipole that can be used (with tuner) on all bands 160 to 10. I have about 8" of ferrite sleeves at the point where the coax transitions to the ladder line. The coax center is connected to one side of the ladder line and the shield is connected to the other side. I have the section with the sleeves in an old plastic jug to provide a little weather protection. Rain still gets in but the sleeves never are immersed. You can find the sleeves at most hamfests, usually for about a dollar apiece (one stand had them at 3 for a buck and I scarfed up as many as I could). 73,
Bill N3WK

George Bush conspired with Gov. Pataki to keep John McCain, Steve Forbes, and his other competitors off the ballot in the Republican primary in New York State. They nearly succeeded until a federal judge embarrassed them into giving up this crassly antidemocratic effort.

If Bush had his way, you would have no vote. His would be the only name on the ballot.

And you think he's for personal freedoms?

Sounds like a real 'hot' installation! To impress, you could always claim on QSLs, that your feedline 'burnt up'!

> or a flattop for 80 mtrs feed it with coax ...

Opinions are one thing - physics is another. Your above configuration (with coax all the way to the dipole) is much worse advice than the G5RV on the bands where the G5RV performs well, i.e. 80m, 40m, 20m, 15m, and 12m. According to EZNEC, the 300 ohm series section transformer (matching section) lowers the 50 ohm SWR from 69:1 to 3.4:1 on 80m, from 64:1 to 4.3:1 on 40m, from 74:1 to 7.8:1 on 15m, and from 15:1 to 2.2:1 on 12m. Take a few minutes to calculate the relative losses in the coax due to SWR and you will see that the G5RV beats your antidotal advice all to heck. A good rule of thumb is not to run more than 50 ft of coax with an SWR higher than 10:1.

Hello,
I am interested in purchasing the Radio Shack 10 meter mobile and mounting in my pickup. I have been using UHF & VHF in my vehicles for a long time but I have no experience with HF in the car. I have two questions:

1) Can you recommend a 10 meter antenna to me?

2) Do I have to do anything different when installing an HF system (25 watts) in my vehicle?

3) Any other suggestions/issues would be greatly appreciated!

Thanks in Advance

The most choking action for the money, IMO, is ten turns of
RG-400 (teflon) wrapped on a $9 Amidon FT-240-61 ferrite core.

So much for the availability- now - how about the "peers"?

English majors to check spelling, punctuation and syntax.
Math majors to check notation and derivation.
Librarians to check attribution?
Art majors to critique the figures?
MBA's to see if the bottom line is red or black?

Which will it be? will we ever know?

Hope this helps.

Bill-W4BSG

Thanks everyone for your replies.

I thought I did everything right; here is how I arrived at -25dBm (power relative to one milliwatt).

First, I converted the published transmitter power to EIRP

As listed by the FCC, the transmitter power is 100kW ERP, which equals 80dBm. I added 2.14dB to get 82.14dBm for EIRP. I'm told this is a standard conversion value. This will be 'Pt' below.

For path loss (Lp), I used Lp = 32.4 + 20log(f) + 20log(d), with f in MHz and d in km. For my location and channel 2; Lp = 32.4 + 20log(55.25) + 20log(191.1815) = 112.876dB
